# Periodic solutions for evolution equations * 

Mihai Bostan

#### Abstract

We study the existence and uniqueness of periodic solutions for evolution equations. First we analyze the one-dimensional case. Then for arbitrary dimensions (finite or not), we consider linear symmetric operators. We also prove the same results for non-linear sub-differential operators $A=\partial \varphi$ where $\varphi$ is convex.

## 1 Introduction

Many theoretical and numerical studies in applied mathematics focus on permanent regimes for ordinary or partial differential equations. The main purpose of this paper is to establish existence and uniqueness results for periodic solutions in the general framework of evolution equations,

$$
\begin{equation*}
x^{\prime}(t)+A x(t)=f(t), \quad t \in \mathbb{R} \tag{1}
\end{equation*}
$$

[^0]by using the penalization method. Note that in the linear case a necessary condition for the existence is
\[

$$
\begin{equation*}
\langle f\rangle:=\frac{1}{T} \int_{0}^{T} f(t) d t \in \operatorname{Range}(A) \tag{2}
\end{equation*}
$$

\]

Unfortunately, this condition is not always sufficient for existence; see the example of the orthogonal rotation of $\mathbb{R}^{2}$. Nevertheless, the condition (2) is sufficient in the symmetric case. The key point consists of considering first the perturbed equation

$$
\alpha x_{\alpha}(t)+x_{\alpha}^{\prime}(t)+A x_{\alpha}(t)=f(t), \quad t \in \mathbb{R},
$$

where $\alpha>0$. By using the Banach's fixed point theorem we deduce the existence and uniqueness of the periodic solutions $x_{\alpha}, \alpha>0$. Under the assumption (2), in the linear symmetric case we show that $\left(x_{\alpha}\right)_{\alpha>0}$ is a Cauchy sequence in $C^{1}$. Then by passing to the limit for $\alpha \rightarrow 0$ it follows that the limit function is a periodic solution for (1).

These results have been announced in [2]. The same approach applies for the study of almost periodic solutions (see [3]). Results concerning this topic have been obtained previously by other authors using different methods. A similar condition (2) has been investigated in [5] when studying the range of sums of monotone operators. A different method consists of applying fixed point techniques, see for example [4, 7].

This article is organized as follows. First we analyze the one dimensional case. Necessary and sufficient conditions for the existence and uniqueness of periodic solutions are shown. Results for sub(super)-periodic solutions are proved as well in this case. In the next section we show that the same existence result holds for linear symmetric maximal monotone operators on Hilbert spaces. In the last section the case of non-linear sub-differential operators is considered.

## 2 Periodic solutions for one dimensional evolution equations

To study the periodic solutions for evolution equations it is convenient to consider first the one dimensional case

$$
\begin{equation*}
x^{\prime}(t)+g(x(t))=f(t), \quad t \in \mathbb{R} \tag{3}
\end{equation*}
$$

where $g: \mathbb{R} \rightarrow \mathbb{R}$ is increasing Lipschitz continuous in $x$ and $f: \mathbb{R} \rightarrow \mathbb{R}$ is $T$-periodic and continuous in $t$. By Picard's theorem it follows that for each initial data $x(0)=x_{0} \in \mathbb{R}$ there is an unique solution $x \in C^{1}(\mathbb{R} ; \mathbb{R})$ for (3). We are looking for $T$-periodic solutions. Let us start by the uniqueness study.

### 2.1 Uniqueness

Proposition 2.1 Assume that $g$ is strictly increasing and $f$ is periodic. Then there is at most one periodic solution for (3).

Proof Let $x_{1}, x_{2}$ be two periodic solutions for (3). By taking the difference between the two equations and multiplying by $x_{1}(t)-x_{2}(t)$ we get

$$
\begin{equation*}
\frac{1}{2} \frac{d}{d t}\left|x_{1}(t)-x_{2}(t)\right|^{2}+\left[g\left(x_{1}(t)\right)-g\left(x_{2}(t)\right)\right]\left[x_{1}(t)-x_{2}(t)\right]=0, \quad t \in \mathbb{R} \tag{4}
\end{equation*}
$$

Since $g$ is increasing we have $\left(g\left(x_{1}\right)-g\left(x_{2}\right)\right)\left(x_{1}-x_{2}\right) \geq 0$ for all $x_{1}, x_{2} \in \mathbb{R}$ and therefore we deduce that $\left|x_{1}(t)-x_{2}(t)\right|$ is decreasing. Moreover as $x_{1}$ and $x_{2}$ are periodic it follows that $\left|x_{1}(t)-x_{2}(t)\right|$ does not depend on $t \in \mathbb{R}$ and therefore, from (4) we get

$$
\left[g\left(x_{1}(t)\right)-g\left(x_{2}(t)\right)\right]\left[x_{1}(t)-x_{2}(t)\right]=0, \quad t \in \mathbb{R} .
$$

Finally, the strictly monotony of $g$ implies that $x_{1}=x_{2}$.
Remark 2.2 If $g$ is only increasing, it is possible that (3) has several periodic solutions. Let us consider the function

$$
g(x)= \begin{cases}x+\varepsilon & x<-\varepsilon  \tag{5}\\ 0 & x \in[-\varepsilon, \varepsilon] \\ x-\varepsilon & x>\varepsilon,\end{cases}
$$

and $f(t)=\frac{\varepsilon}{2} \cos t$. We can easily check that $x_{\lambda}(t)=\lambda+\frac{\varepsilon}{2} \sin t$ are periodic solutions for (3) for $\lambda \in\left[-\frac{\varepsilon}{2}, \frac{\varepsilon}{2}\right]$.

Generally we can prove that every two periodic solutions differ by a constant.
Proposition 2.3 Let $g$ be an increasing function and $x_{1}, x_{2}$ two periodic solutions of (3). Then there is a constant $C \in \mathbb{R}$ such that

$$
x_{1}(t)-x_{2}(t)=C, \quad \forall t \in \mathbb{R} .
$$

Proof As shown before there is a constant $C \in \mathbb{R}$ such that $\left|x_{1}(t)-x_{2}(t)\right|=C$, $t \in \mathbb{R}$. Moreover $x_{1}(t)-x_{2}(t)$ has constant sign, otherwise $x_{1}\left(t_{0}\right)=x_{2}\left(t_{0}\right)$ for some $t_{0} \in \mathbb{R}$ and it follows that $\left|x_{1}(t)-x_{2}(t)\right|=\left|x_{1}\left(t_{0}\right)-x_{2}\left(t_{0}\right)\right|=0, t \in \mathbb{R}$ or $x_{1}=x_{2}$. Finally we find that

$$
x_{1}(t)-x_{2}(t)=\operatorname{sign}\left(x_{1}(0)-x_{2}(0)\right) C, \quad t \in \mathbb{R} .
$$

Before analyzing in detail the uniqueness for increasing functions, let us define the following sets.
$\mathcal{O}(y)= \begin{cases}\left\{x \in \mathbb{R}: x+\int_{0}^{t}(f(s)-y) d s \in g^{-1}(y) \forall t \in \mathbb{R}\right\} \subset g^{-1}(y), & y \in g(\mathbb{R}), \\ \emptyset, & y \notin g(\mathbb{R}) .\end{cases}$
Proposition 2.4 Let $g$ be an increasing function and $f$ periodic. Then equation (3) has different periodic solutions if and only if $\operatorname{Int}(\mathcal{O}\langle f\rangle) \neq \emptyset$.

Proof Assume that (3) has two periodic solutions $x_{1} \neq x_{2}$. By the previous proposition we have $x_{2}-x_{1}=C>0$. By integration on $[0, T]$ one gets

$$
\begin{equation*}
\int_{0}^{T} g\left(x_{1}(t)\right) d t=\int_{0}^{T} f(t) d t=\int_{0}^{T} g\left(x_{2}(t)\right) d t \tag{6}
\end{equation*}
$$

Since $g$ is increasing we have $g\left(x_{1}(t)\right) \leq g\left(x_{2}(t)\right), \quad t \in \mathbb{R}$ and therefore,

$$
\begin{equation*}
\int_{0}^{T} g\left(x_{1}(t)\right) d t \leq \int_{0}^{T} g\left(x_{2}(t)\right) d t \tag{7}
\end{equation*}
$$

From (6) and (7) we deduce that $g\left(x_{1}(t)\right)=g\left(x_{2}(t)\right), t \in \mathbb{R}$ and thus $g$ is constant on each interval $\left[x_{1}(t), x_{2}(t)\right]=\left[x_{1}(t), x_{1}(t)+C\right], t \in \mathbb{R}$. Finally it implies that $g$ is constant on Range $\left(x_{1}\right)+[0, C]=\left\{x_{1}(t)+y: t \in[0, T], y \in\right.$ $[0, C]\}$ and this constant is exactly the time average of $f$ :

$$
g\left(x_{1}(t)\right)=g\left(x_{2}(t)\right)=\langle f\rangle, \quad t \in[0, T] .
$$

Let $x$ be an arbitrary real number in $] x_{1}(0), x_{1}(0)+C[$. Then

$$
\begin{aligned}
x+\int_{0}^{t}\{f(s)-\langle f\rangle\} d s & =x-x_{1}(0)+x_{1}(0)+\int_{0}^{t}\left\{f(s)-g\left(x_{1}(s)\right)\right\} d s \\
& =x-x_{1}(0)+x_{1}(t) \\
& >x_{1}(t), \quad t \in \mathbb{R}
\end{aligned}
$$

Similarly,

$$
\begin{aligned}
x+\int_{0}^{t}\{f(s)-\langle f\rangle\} d s & =x-x_{2}(0)+x_{2}(0)+\int_{0}^{t}\left\{f(s)-g\left(x_{2}(s)\right)\right\} d s \\
& =x-x_{2}(0)+x_{2}(t) \\
& <x_{2}(t), \quad t \in \mathbb{R}
\end{aligned}
$$

Therefore, $\left.x+\int_{0}^{t}\{f(s)-\langle f\rangle\} d s \in\right] x_{1}(t), x_{2}(t)\left[\subset g^{-1}(\langle f\rangle), \quad t \in \mathbb{R}\right.$ which implies that $x \in \mathcal{O}\langle f\rangle$ and hence $] x_{1}(0), x_{2}(0)[\subset \mathcal{O}\langle f\rangle$.
Conversely, suppose that there is $x$ and $C>0$ small enough such that $x, x+C \in$ $\mathcal{O}\langle f\rangle$. It is easy to check that $x_{1}, x_{2}$ given below are different periodic solutions for (3):

$$
\begin{gathered}
x_{1}(t)=x+\int_{0}^{t}\{f(s)-\langle f\rangle\} d s, \quad t \in \mathbb{R}, \\
x_{2}(t)=x+C+\int_{0}^{t}\{f(s)-\langle f\rangle\} d s=x_{1}(t)+C, \quad t \in \mathbb{R} .
\end{gathered}
$$

Remark 2.5 The condition $\operatorname{Int}(\mathcal{O}\langle f\rangle) \neq \emptyset$ is equivalent to

$$
\operatorname{diam}\left(g^{-1}\langle f\rangle\right)>\operatorname{diam}\left(\text { Range } \int\{f(t)-\langle f\rangle\} d t\right)
$$

Example: Consider the equation $x^{\prime}(t)+g(x(t))=\eta \cos t, t \in \mathbb{R}$ with $g$ given in Remark 2.2. We have $<\eta \cos t>=0 \in g(\mathbb{R})$ and

$$
\begin{align*}
\mathcal{O}(0) & =\left\{x \in \mathbb{R} \mid x+\int_{0}^{t} \eta \cos s d s \in g^{-1}(0), \quad t \in \mathbb{R}\right\}  \tag{8}\\
& =\left\{x \in \mathbb{R}: x+\eta \sin t \in g^{-1}(0), \quad t \in \mathbb{R}\right\} \\
& =\{x \in \mathbb{R}:-\varepsilon \leq x+\eta \sin t \leq \varepsilon, t \in \mathbb{R}\} \\
& = \begin{cases}\emptyset & |\eta|>\varepsilon, \\
\{0\} & |\eta|=\varepsilon, \\
{[|\eta|-\varepsilon, \varepsilon-|\eta|]} & |\eta|<\varepsilon .\end{cases} \tag{9}
\end{align*}
$$

Therefore, uniqueness does not occur if $|\eta|<\varepsilon$, for example if $\eta=\varepsilon / 2$, as seen before in Remark 2.2. If $|\eta| \geq \varepsilon$ there is an unique periodic solution.

In the following we suppose that $g$ is increasing and we establish an existence result.

### 2.2 Existence

To study the existence, note that a necessary condition is given by the following proposition.

Proposition 2.6 Assume that equation (3) has T-periodic solutions. Then there is $x_{0} \in \mathbb{R}$ such that $\langle f\rangle:=\frac{1}{T} \int_{0}^{T} f(t) d t=g\left(x_{0}\right)$.

Proof Integrating on a period interval $[0, T]$ we obtain

$$
x(T)-x(0)+\int_{0}^{T} g(x(t)) d t=\int_{0}^{T} f(t) d t
$$

Since $x$ is periodic and $g \circ x$ is continuous we get

$$
\left.T g(x(\tau))=\int_{0}^{T} f(t) d t, \quad \tau \in\right] 0, T[
$$

and hence

$$
\begin{equation*}
\langle f\rangle:=\frac{1}{T} \int_{0}^{T} f(t) d t \in \operatorname{Range}(g) \tag{10}
\end{equation*}
$$

In the following we will show that this condition is also sufficient for the existence of periodic solutions. We will prove this result in several steps. First we establish the existence for the equation

$$
\begin{equation*}
\alpha x_{\alpha}(t)+x_{\alpha}^{\prime}(t)+g\left(x_{\alpha}(t)\right)=f(t), \quad t \in \mathbb{R}, \quad \alpha>0 . \tag{11}
\end{equation*}
$$

Proposition 2.7 Suppose that $g$ is increasing Lipschitz continuous and $f$ is $T$-periodic and continuous. Then for every $\alpha>0$ the equation (11) has exactly one periodic solution.

Remark 2.8 Before starting the proof let us observe that (11) reduces to an equation of type (3) with $g_{\alpha}=\alpha 1_{\mathbb{R}}+g$. Since $g$ is increasing, is clear that $g_{\alpha}$ is strictly increasing and by the Proposition 2.1 we deduce that the uniqueness holds. Moreover since Range $\left(g_{\alpha}\right)=\mathbb{R}$, the necessary condition (10) is trivially verified and therefore, in this case we can expect to prove existence.

Proof First of all remark that the existence of periodic solutions reduces to finding $x_{0} \in \mathbb{R}$ such that the solution of the evolution problem

$$
\begin{align*}
\alpha x_{\alpha}(t)+x_{\alpha}^{\prime}(t)+ & g\left(x_{\alpha}(t)\right)=f(t), \quad t \in[0, T]  \tag{12}\\
& x(0)=x_{0}
\end{align*}
$$

verifies $x\left(T ; 0, x_{0}\right)=x_{0}$. Here we denote by $x\left(\cdot ; 0, x_{0}\right)$ the solution of (12) (existence and uniqueness assured by Picard's theorem). We define the map $S: \mathbb{R} \rightarrow \mathbb{R}$ given by

$$
\begin{equation*}
S\left(x_{0}\right)=x\left(T ; 0, x_{0}\right), \quad x_{0} \in \mathbb{R} \tag{13}
\end{equation*}
$$

We demonstrate the existence and uniqueness of the periodic solution of (12) by showing that the Banach's fixed point theorem applies. Let us consider two solutions of (12) corresponding to the initial datas $x_{0}^{1}$ and $x_{0}^{2}$. Using the monotony of $g$ we can write

$$
\alpha\left|x\left(t ; 0, x_{0}^{1}\right)-x\left(t ; 0, x_{0}^{2}\right)\right|^{2}+\frac{1}{2} \frac{d}{d t}\left|x\left(t ; 0, x_{0}^{1}\right)-x\left(t ; 0, x_{0}^{2}\right)\right|^{2} \leq 0
$$

which implies

$$
\frac{1}{2} \frac{d}{d t}\left\{e^{2 \alpha t}\left|x\left(t ; 0, x_{0}^{1}\right)-x\left(t ; 0, x_{0}^{2}\right)\right|^{2}\right\} \leq 0
$$

and therefore,

$$
\left|S\left(x_{0}^{1}\right)-S\left(x_{0}^{2}\right)\right|=\left|x\left(T ; 0, x_{0}^{1}\right)-x\left(T ; 0, x_{0}^{2}\right)\right| \leq e^{-\alpha T}\left|x_{0}^{1}-x_{0}^{2}\right|
$$

For $\alpha>0 S$ is a contraction and the Banach's fixed point theorem applies. Therefore $S\left(x_{0}\right)=x_{0}$ for an unique $x_{0} \in \mathbb{R}$ and hence $x\left(\cdot ; 0, x_{0}\right)$ is a periodic solution of (3).

Naturally, in the following proposition we inquire about the convergence of $\left(x_{\alpha}\right)_{\alpha>0}$ to a periodic solution of (3) as $\alpha \rightarrow 0$. In view of the Proposition 2.6 this convergence does not hold if (10) is not verified. Assume for the moment that (3) has at least one periodic solution. In this case convergence holds.

Proposition 2.9 If equation (3) has at least one periodic solution, then $\left(x_{\alpha}\right)_{\alpha>0}$ is convergent in $C^{0}(\mathbb{R} ; \mathbb{R})$ and the limit is also a periodic solution of (3).

Proof Denote by $x$ a periodic solution of (3). By elementary calculations we find

$$
\begin{equation*}
\alpha\left|x_{\alpha}(t)-x(t)\right|^{2}+\frac{1}{2} \frac{d}{d t}\left|x_{\alpha}(t)-x(t)\right|^{2} \leq-\alpha x(t)\left(x_{\alpha}(t)-x(t)\right), \quad t \in \mathbb{R} \tag{17}
\end{equation*}
$$

which can be also written as

$$
\begin{equation*}
\frac{1}{2} \frac{d}{d t}\left\{e^{2 \alpha t}\left|x_{\alpha}(t)-x(t)\right|^{2}\right\} \leq \alpha e^{\alpha t}|x(t)| \cdot e^{\alpha t}\left|x_{\alpha}(t)-x(t)\right|, \quad t \in \mathbb{R} \tag{18}
\end{equation*}
$$

Therefore, by integration on $[0, t]$ we deduce

$$
\begin{equation*}
\frac{1}{2}\left\{e^{\alpha t}\left|x_{\alpha}(t)-x(t)\right|\right\}^{2} \leq \frac{1}{2}\left|x_{\alpha}(0)-x(0)\right|^{2}+\int_{0}^{t} \alpha e^{\alpha s}|x(s)| \cdot e^{\alpha s}\left|x_{\alpha}(s)-x(s)\right| d s \tag{19}
\end{equation*}
$$

Using Bellman's lemma, formula (19) gives

$$
\begin{equation*}
e^{\alpha t}\left|x_{\alpha}(t)-x(t)\right| \leq\left|x_{\alpha}(0)-x(0)\right|+\int_{0}^{t} \alpha e^{\alpha s}|x(s)| d s, \quad t \in \mathbb{R} . \tag{20}
\end{equation*}
$$

Let us consider $\alpha>0$ fixed for the moment. Since $x$ is periodic and continuous, it is also bounded and therefore from (20) we get

$$
\begin{equation*}
\left|x_{\alpha}(t)-x(t)\right| \leq e^{-\alpha t}\left|x_{\alpha}(0)-x(0)\right|+\left(1-e^{-\alpha t}\right)\|x\|_{L^{\infty}(\mathbb{R})}, \quad t \in \mathbb{R} . \tag{21}
\end{equation*}
$$

By periodicity we have

$$
\begin{aligned}
\left|x_{\alpha}(t)-x(t)\right| & =\left|x_{\alpha}(n T+t)-x(n T+t)\right| \\
& \leq e^{-\alpha(n T+t)}\left|x_{\alpha}(0)-x(0)\right|+\left(1-e^{-\alpha(n T+t)}\right)\|x\|_{L^{\infty}(\mathbb{R})} \\
& \leq e^{-\alpha(n T+t)}\left|x_{\alpha}(0)-x(0)\right|+\|x\|_{L^{\infty}(\mathbb{R})}, \quad t \in \mathbb{R}, n \geq 0 .
\end{aligned}
$$

By passing to the limit as $n \rightarrow \infty$, we deduce that $\left(x_{\alpha}\right)_{\alpha>0}$ is uniformly bounded in $L^{\infty}(\mathbb{R})$ :

$$
\left|x_{\alpha}(t)\right| \leq\left|x_{\alpha}(t)-x(t)\right|+|x(t)| \leq 2\|x\|_{L^{\infty}(\mathbb{R})}, \quad t \in \mathbb{R}, \alpha>0 .
$$

The derivatives $x_{\alpha}^{\prime}$ are also uniformly bounded in $L^{\infty}(\mathbb{R})$ for $\alpha \rightarrow 0$ :

$$
\begin{aligned}
& \left|x_{\alpha}^{\prime}(t)\right| \\
& \quad=\left|f(t)-\alpha x_{\alpha}(t)-g\left(x_{\alpha}(t)\right)\right| \\
& \quad \leq\|f\|_{L^{\infty}(\mathbb{R})}+2 \alpha\|x\|_{L^{\infty}(\mathbb{R})}+\max \left\{g\left(2\|x\|_{L^{\infty}(\mathbb{R})}\right),-g\left(-2\|x\|_{L^{\infty}(\mathbb{R})}\right)\right\} .
\end{aligned}
$$

The uniform convergence of $\left(x_{\alpha}\right)_{\alpha>0}$ follows now from the Arzela-Ascoli's theorem. Denote by $u$ the limit of $\left(x_{\alpha}\right)_{\alpha>0}$ as $\alpha \rightarrow 0$. Obviously $u$ is also periodic

$$
u(0)=\lim _{\alpha \rightarrow 0} x_{\alpha}(0)=\lim _{\alpha \rightarrow 0} x_{\alpha}(T)=u(T)
$$

To prove that $u$ verifies (3), we write

$$
x_{\alpha}(t)=x_{\alpha}(0)+\int_{0}^{t}\left\{f(s)-g\left(x_{\alpha}(s)\right)-\alpha x_{\alpha}(s)\right\} d s, \quad t \in \mathbb{R} .
$$

Since the convergence is uniform, by passing to the limit for $\alpha \rightarrow 0$ we obtain

$$
u(t)=u(0)+\int_{0}^{t}\{f(s)-g(u(s))\} d s
$$

and hence $u \in C^{1}(\mathbb{R} ; \mathbb{R})$ and

$$
u^{\prime}(t)+g(u(t))=f(t), \quad t \in \mathbb{R}
$$

From the previous proposition we conclude that the existence of periodic solutions for (3) reduces to uniform estimates in $L^{\infty}(\mathbb{R})$ for $\left(x_{\alpha}\right)_{\alpha>0}$.

Proposition 2.10 Assume that $g$ is increasing Lipschitz continuous and $f$ is $T$-periodic and continuous. Then the following statements are equivalent:
(i) equation (3) has periodic solutions;
(ii) the sequence $\left(x_{\alpha}\right)_{\alpha>0}$ is uniformly bounded in $L^{\infty}(\mathbb{R})$. Moreover, in this case $\left(x_{\alpha}\right)_{\alpha>0}$ is convergent in $C^{0}(\mathbb{R} ; \mathbb{R})$ and the limit is a periodic solution for (3).

Note that generally we can not estimate $\left(x_{\alpha}\right)_{\alpha>0}$ uniformly in $L^{\infty}(\mathbb{R})$. Indeed, by standard computations we obtain

$$
\alpha\left(x_{\alpha}(t)-u\right)^{2}+\frac{1}{2} \frac{d}{d t}\left(x_{\alpha}(t)-u\right)^{2} \leq|f(t)-\alpha u-g(u)| \cdot\left|x_{\alpha}(t)-u\right|, \quad t, u \in \mathbb{R}
$$

and therefore

$$
\frac{1}{2} \frac{d}{d t}\left\{e^{2 \alpha t}\left(x_{\alpha}(t)-u\right)^{2}\right\} \leq e^{\alpha t}|f(t)-\alpha u-g(u)| \cdot e^{\alpha t}\left|x_{\alpha}(t)-u\right|, \quad t, u \in \mathbb{R}
$$

Integration on $[t, t+h]$, we get

$$
\begin{aligned}
\frac{1}{2} e^{2 \alpha(t+h)}\left(x_{\alpha}(t+h)-u\right)^{2} \leq & \int_{t}^{t+h} e^{2 \alpha s}|f(s)-\alpha u-g(u)| \cdot\left|x_{\alpha}(s)-u\right| d s \\
& +\frac{1}{2} e^{2 \alpha t}\left(x_{\alpha}(t)-u\right)^{2}, \quad t<t+h, u \in \mathbb{R}
\end{aligned}
$$

Now by using Bellman's lemma we deduce

$$
\left|x_{\alpha}(t+h)-u\right| \leq e^{-\alpha h}\left|x_{\alpha}(t)-u\right|+\int_{t}^{t+h} e^{-\alpha(t+h-s)}|f(s)-\alpha u-g(u)| d s, \quad t<t+h .
$$

Since $x_{\alpha}$ is $T$-periodic, by taking $h=T$ we can write

$$
\left|x_{\alpha}(t)-u\right| \leq \frac{1}{1-e^{-\alpha T}} \int_{0}^{T} e^{-\alpha(T-s)}|f(s)-\alpha u-g(u)| d s, \quad t \in \mathbb{R}
$$

and thus for $u=0$ we obtain

$$
\left\|x_{\alpha}\right\|_{L^{\infty}(\mathbb{R})} \leq \frac{1}{1-e^{-\alpha T}} \int_{0}^{T}|f(s)-g(0)| d s \sim \mathcal{O}\left(\frac{1}{\alpha}\right), \quad \alpha>0
$$

Now we can state our main existence result.

Theorem 2.11 Assume that $g$ is increasing Lipschitz continuous, and $f$ is $T$ periodic and continuous. Then equation (3) has periodic solutions if and only if $\langle f\rangle:=\frac{1}{T} \int_{0}^{T} f(t) d t \in \operatorname{Range}(g)$ (there is $x_{0} \in \mathbb{R}$ such that $\langle f\rangle=g\left(x_{0}\right)$ ). Moreover in this case we have the estimate

$$
\|x\|_{L^{\infty}(\mathbb{R})} \leq\left|x_{0}\right|+\int_{0}^{T}|f(t)-\langle f\rangle| d t, \quad \forall x_{0} \in g^{-1}\langle f\rangle
$$

and the solution is unique if and only if $\operatorname{Int}(\mathcal{O}\langle f\rangle)=\emptyset$ or

$$
\operatorname{diam}\left(g^{-1}\langle f\rangle\right) \leq \operatorname{diam}\left(\text { Range } \int\{f(t)-\langle f\rangle\} d t\right)
$$

Proof The condition is necessary (see Proposition 2.6). We will prove now that it is also sufficient. Let us consider the sequence of periodic solutions $\left(x_{\alpha}\right)_{\alpha>0}$ of (11). Accordingly to the Proposition 2.10 we need to prove uniform estimates in $L^{\infty}(\mathbb{R})$ for $\left(x_{\alpha}\right)_{\alpha>0}$. Since $x_{\alpha}$ is $T$-periodic by integration on $[0, T]$ we get

$$
\int_{0}^{T}\left\{\alpha x_{\alpha}(t)+g\left(x_{\alpha}(t)\right)\right\} d t=T\langle f\rangle, \quad \alpha>0 .
$$

Using the average formula for continuous functions we have

$$
\left.\int_{0}^{T}\left\{\alpha x_{\alpha}(t)+g\left(x_{\alpha}(t)\right)\right\} d t=T\left\{\alpha x_{\alpha}\left(t_{\alpha}\right)+g\left(x_{\alpha}\left(t_{\alpha}\right)\right)\right\}, \quad t_{\alpha} \in\right] 0, T[, \alpha>0 .
$$

By the hypothesis there is $x_{0} \in \mathbb{R}$ such that $\langle f\rangle=g\left(x_{0}\right)$ and thus

$$
\begin{equation*}
\alpha x_{\alpha}\left(t_{\alpha}\right)+g\left(x_{\alpha}\left(t_{\alpha}\right)\right)=g\left(x_{0}\right), \quad \alpha>0 . \tag{22}
\end{equation*}
$$

Since $g$ is increasing, we deduce

$$
\alpha x_{\alpha}\left(t_{\alpha}\right)\left[x_{0}-x_{\alpha}\left(t_{\alpha}\right)\right]=\left[g\left(x_{0}\right)-g\left(x_{\alpha}\left(t_{\alpha}\right)\right)\right]\left[x_{0}-x_{\alpha}\left(t_{\alpha}\right)\right] \geq 0, \quad \alpha>0,
$$

and thus

$$
\left|x_{\alpha}\left(t_{\alpha}\right)\right|^{2} \leq x_{\alpha}\left(t_{\alpha}\right) x_{0} \leq\left|x_{\alpha}\left(t_{\alpha}\right)\right|\left|x_{0}\right| .
$$

Finally we deduce that $x_{\alpha}\left(t_{\alpha}\right)$ is uniformly bounded in $\mathbb{R}$ :

$$
\left|x_{\alpha}\left(t_{\alpha}\right)\right| \leq\left|x_{0}\right|, \quad \forall \alpha>0 .
$$

Now we can easily find uniform estimates in $L^{\infty}(\mathbb{R})$ for $\left(x_{\alpha}\right)_{\alpha>0}$. Let us take in the previous calculus $u=x_{\alpha}\left(t_{\alpha}\right)$ and integrate on $\left[t_{\alpha}, t\right]$ :
$\frac{1}{2} e^{2 \alpha t}\left(x_{\alpha}(t)-x_{\alpha}\left(t_{\alpha}\right)\right)^{2} \leq \int_{t_{\alpha}}^{t} e^{2 \alpha s}\left|f(s)-\alpha x_{\alpha}\left(t_{\alpha}\right)-g\left(x_{\alpha}\left(t_{\alpha}\right)\right)\right| \cdot\left|x_{\alpha}(s)-x_{\alpha}\left(t_{\alpha}\right)\right| d s$.
By using Bellman's lemma we get

$$
\left|x_{\alpha}(t)-x_{\alpha}\left(t_{\alpha}\right)\right| \leq \int_{t_{\alpha}}^{t} e^{-\alpha(t-s)}\left|f(s)-\alpha x_{\alpha}\left(t_{\alpha}\right)-g\left(x_{\alpha}\left(t_{\alpha}\right)\right)\right| d s, \quad t>t_{\alpha}
$$

and hence by (22) we deduce

$$
\begin{align*}
\left|x_{\alpha}(t)\right| & \leq\left|x_{0}\right|+\int_{0}^{T}\left|f(t)-\alpha x_{\alpha}\left(t_{\alpha}\right)-g\left(x_{\alpha}\left(t_{\alpha}\right)\right)\right| d t \\
& =\left|x_{0}\right|+\int_{0}^{T}|f(t)-\langle f\rangle| d t, \quad t \in \mathbb{R}, \alpha>0 \tag{23}
\end{align*}
$$

Now by passing to the limit in (23) we get

$$
|x(t)| \leq\left|x_{0}\right|+\int_{0}^{T}|f(t)-\langle f\rangle| d t, \quad t \in \mathbb{R}, \forall x_{0} \in g^{-1}\langle f\rangle
$$

### 2.3 Sub(super)-periodic solutions

In this part we generalize the previous existence results for sub(super)-periodic solutions. We will see that similar results hold. Let us introduce the concept of sub(super)-periodic solutions.

Definition 2.12 We say that $x \in C^{1}([0, T] ; \mathbb{R})$ is a sub-periodic solution for (3) if

$$
x^{\prime}(t)+g(x(t))=f(t), \quad t \in[0, T]
$$

and $x(0) \leq x(T)$.
Note that a necessary condition for the existence is given next.
Proposition 2.13 If equation (3) has sub-periodic solutions, then there is $x_{0} \in$ $\mathbb{R}$ such that $g\left(x_{0}\right) \leq\langle f\rangle$.

Proof Let $x$ be a sub-periodic solution of (3). By integration on $[0, T]$ we find

$$
x(T)-x(0)+\int_{0}^{T} g(x(t)) d t=T\langle f\rangle
$$

Since $g \circ x$ is continuous, there is $\tau \in] 0, T[$ such that

$$
g(x(\tau))=\langle f\rangle-\frac{1}{T}(x(T)-x(0)) \leq\langle f\rangle
$$

Similarly we define the notion of super-periodic solution.
Definition 2.14 We say that $y \in C^{1}([0, T] ; \mathbb{R})$ is a super-periodic solution for (3) if

$$
y^{\prime}(t)+g(y(t))=f(t), \quad t[0, T]
$$

and $y(0) \geq y(T)$.
The analogous necessary condition holds.

Proposition 2.15 If equation (3) has super-periodic solutions, then there is $y_{0} \in \mathbb{R}$ such that $g\left(y_{0}\right) \geq\langle f\rangle$.

Remark 2.16 It is clear that $x$ is periodic solution for (3) if and only if is in the same time sub-periodic and super-periodic solution. Therefore there are $x_{0}, y_{0} \in \mathbb{R}$ such that

$$
g\left(x_{0}\right) \leq\langle f\rangle \leq g\left(y_{0}\right)
$$

Since $g$ is continuous, we deduce that $\langle f\rangle \in \operatorname{Range}(g)$ which is exactly the necessary condition given by the Proposition 2.6.

As before we will prove that the necessary condition of Proposition 2.13 is also sufficient for the existence of sub-periodic solutions.

Theorem 2.17 Assume that $g$ is increasing Lipschitz continuous and $f$ is $T$ periodic continuous. Then equation (3) has sub-periodic solutions if and only if there is $x_{0} \in \mathbb{R}$ such that $g\left(x_{0}\right) \leq\langle f\rangle$.

Proof The condition is necessary (see Proposition 2.13). Let us prove now that it is also sufficient. Consider $z_{0}$ an arbitrary initial data and denote by $x:\left[0, \infty\left[\rightarrow \mathbb{R}\right.\right.$ the solution for (3) with the initial condition $x(0)=z_{0}$. If there is $t_{0} \geq 0$ such that $x\left(t_{0}\right) \leq x\left(t_{0}+T\right)$, thus $x_{t_{0}}(t):=x\left(t_{0}+t\right), t \in[0, T]$ is a sub-periodic solution. Suppose now that $x(t)>x(t+T), \forall t \in \mathbb{R}$. By integration on $[n T,(n+1) T], n \geq 0$ we get

$$
x((n+1) T)-x(n T)+\int_{0}^{T} g(x(n T+t)) d t=T\langle f\rangle, n \geq 0 .
$$

Using the hypothesis and the average formula we have

$$
g\left(x\left(n T+\tau_{n}\right)\right)=\langle f\rangle+\frac{1}{T}\{x(n T)-x((n+1) T)\}>g\left(x_{0}\right)
$$

for $\left.\tau_{n} \in\right] 0, T\left[\right.$ and $n \geq 0$. Since $g$ is increasing we deduce that $x\left(n T+\tau_{n}\right)>$ $x_{0}, n \geq 0$. We have also $x\left(n T+\tau_{n}\right) \leq x\left((n-1) T+\tau_{n}\right) \leq \cdots \leq x\left(\tau_{n}\right) \leq$ $\sup _{t \in[0, T]}|x(t)|$ and thus we deduce that $\left(x\left(n T+\tau_{n}\right)\right)_{n \geq 0}$ is bounded:

$$
\left|x\left(n T+\tau_{n}\right)\right| \leq K, \quad n \geq 0
$$

Consider now the functions $x_{n}:[0, T] \rightarrow \mathbb{R}$ given by

$$
x_{n}(t)=x(n T+t), \quad t \in[0, T] .
$$

By a standard computation we get

$$
\frac{1}{2} \frac{d}{d t}\left|x_{n}(t)\right|^{2}+\left[g\left(x_{n}(t)\right)-g(0)\right] x_{n}(t)=[f(t)-g(0)] x_{n}(t), \quad t \in[0, T] .
$$

Using the monotony of $g$ we obtain

$$
\left|x_{n}(t)\right| \leq\left|x_{n}(s)\right|+\int_{s}^{t}|f(u)-g(0)| d u, \quad 0 \leq s \leq t \leq T
$$

Taking $\left.s=\tau_{n} \in\right] 0, T[$ we can write

$$
\left|x_{n}(t)\right| \leq\left|x_{n}\left(\tau_{n}\right)\right|+\int_{\tau_{n}}^{t}|f(u)-g(0)| d u \leq K+\int_{0}^{T}|f(u)-g(0)| d u, t \in\left[\tau_{n}, T\right]
$$

For $t \in\left[0, \tau_{n}\right], n \geq 1$ we have

$$
\begin{aligned}
\left|x_{n}(t)\right|=|x(n T+t)| & \leq\left|x\left((n-1) T+\tau_{n-1}\right)\right|+\int_{(n-1) T+\tau_{n-1}}^{n T+t}|f(u)-g(0)| d u \\
& \leq K+\int_{(n-1) T}^{(n+1) T}|f(u)-g(0)| d u \\
& \leq K+2 \int_{0}^{T}|f(u)-g(0)| d u
\end{aligned}
$$

Therefore, the sequence $\left(x_{n}\right)_{n \geq 0}$ is uniformly bounded in $L^{\infty}(\mathbb{R})$ and

$$
\left\|x_{n}\right\|_{L^{\infty}(\mathbb{R})} \leq K+2 \int_{0}^{T}|f(t)-g(0)| d t:=M
$$

Moreover, $\left(x_{n}^{\prime}\right)_{n \geq 0}$ is also uniformly bounded in $L^{\infty}(\mathbb{R})$. Indeed we have

$$
\left|x_{n}^{\prime}(t)\right|=\left|f(t)-g\left(x_{n}(t)\right)\right| \leq\|f\|_{L^{\infty}(\mathbb{R})}+\max \{g(M),-g(-M)\}
$$

and hence, by Arzela-Ascoli's theorem we deduce that $\left(x_{n}\right)_{n \geq 0}$ converges in $C^{0}([0, T], \mathbb{R}):$

$$
\lim _{n \rightarrow \infty} x_{n}(t)=u(t), \text { uniformly for } t \in[0, T] .
$$

As usual, by passing to the limit for $n \rightarrow \infty$ we find that $u$ is also solution for (3). Moreover since $(x(n T))_{n \geq 0}$ is decreasing and bounded, it is convergent and we can prove that $u$ is periodic:

$$
u(0)=\lim _{n \rightarrow \infty} x_{n}(0)=\lim _{n \rightarrow \infty} x(n T)=\lim _{n \rightarrow \infty} x((n+1) T)=\lim _{n \rightarrow \infty} x_{n}(T)=u(T)
$$

Therefore, $u$ is a sub-periodic solution for (3). An analogous result holds for super-periodic solutions.

Proposition 2.18 Under the same assumptions as in Theorem 2.17 the equation (3) has super-periodic solutions if and only if there is $y_{0} \in \mathbb{R}$ such that $g\left(y_{0}\right) \geq\langle f\rangle$.

We state now a comparison result between sub-periodic and super-periodic solutions.

Proposition 2.19 If $g$ is increasing, $x$ is a sub-periodic solution and $y$ is $a$ super-periodic solution we have

$$
x(t) \leq y(t), \quad \forall t \in[0, T]
$$

provided that $x$ and $y$ are not both periodic.

Proof Both $x$ and $y$ verify (3), thus

$$
(x-y)^{\prime}(t)+g(x(t))-g(y(t))=0, \quad t \in[0, T] .
$$

With the notation

$$
r(t)= \begin{cases}\frac{g(x(t))-g(y(t))}{x(t)-y(t)} & t \in[0, T], x(t) \neq y(t)  \tag{24}\\ 0 & t \in[0, T], x(t)=y(t)\end{cases}
$$

we can write $g(x(t))-g(y(t))=r(t)(x(t)-y(t)), t \in[0, T]$ and therefore,

$$
(x-y)^{\prime}(t)+r(t)(x(t)-y(t))=0, t \in[0, T]
$$

which implies

$$
\begin{equation*}
x(t)-y(t)=(x(0)-y(0)) e^{-\int_{0}^{t} r(s) d s} . \tag{25}
\end{equation*}
$$

Now it is clear that if $x(0) \leq y(0)$ we also have $x(t) \leq y(t), t \in[0, T]$. Suppose now that $x(0)>y(0)$. Taking $t=T$ in (25) we obtain

$$
\begin{equation*}
x(T)-y(T)=(x(0)-y(0)) e^{-\int_{0}^{T} r(t) d t} \tag{26}
\end{equation*}
$$

Since $g$ is increasing, by the definition of the function $r$ we have $r \geq 0$. Two cases are possible: (i) either $\int_{0}^{T} r(t) d t>0$, (ii) either $\int_{0}^{T} r(t) d t=0$ in which case $r(t)=0, t \in[0, T]$ ( $r$ vanishes in all points of continuity $t$ such that $x(t) \neq y(t)$ and also in all points $t$ with $x(t)=y(t)$ by the definition). Let us analyse the first case (i). By (26) we deduce that $x(T)-y(T)<x(0)-y(0)$ or $x(T)-x(0)<y(T)-y(0)$. Since $x$ is sub-periodic we have $x(0) \leq x(T)$ which implies that $y(T)>y(0)$ which is in contradiction with the super-periodicity of $y(y(T) \leq y(0))$.
In the second case (ii) we have $g(x(t))=g(y(t)), t \in[0, T]$ so $(x-y)^{\prime}=0$ and therefore there is a constant $C \in \mathbb{R}$ such that $x(t)=y(t)+C, t \in[0, T]$. Taking $t=0$ and $t=T$ we obtain

$$
0 \geq x(0)-x(T)=y(0)-y(T) \geq 0
$$

and thus $x$ and $y$ are both periodic which is in contradiction with the hypothesis. In the following we will see how it is possible to retrieve the existence result for periodic solutions by using the method of sub(super)-periodic solutions. Suppose that $\langle f\rangle \in \operatorname{Range}(g)$. Obviously both sufficient conditions for existence of sub(super)-periodic solutions are satisfied and thus there are $x_{0}\left(y_{0}\right)$ sub(super)periodic solutions. If $y_{0}$ is even periodic the proof is complete. Assume that $y_{0}$ is not periodic $\left(y_{0}(0)>y_{0}(T)\right)$. Denote by $\mathcal{M}$ the set of sub-periodic solutions for (3):

$$
\mathcal{M}=\left\{x:[0, T] \rightarrow \mathbb{R}: x \text { sub-periodic solution }, \quad x_{0}(t) \leq x(t), t \in[0, T]\right\}
$$

Since $x_{0} \in \mathcal{M}$ we have $\mathcal{M} \neq \emptyset$. Moreover, from the comparison result since $y_{0}$ is super-periodic but not periodic we have $x \leq y_{0}, \forall x \in \mathcal{M}$. We prove that $\mathcal{M}$ contains a maximal element in respect to the order:

$$
x_{1} \prec x_{2} \text { (if and only if) } x_{1}(t) \leq x_{2}(t), \quad t \in[0, T] .
$$

Finally we show that this maximal element is even a periodic solution for (3) since otherwise it would be possible to construct a sub-periodic solution greater than the maximal element. We state now the following generalization.

Theorem 2.20 Assume that $g: \mathbb{R} \times \mathbb{R} \rightarrow \mathbb{R}$ is increasing Lipschitz continuous function in $x$, T-periodic and continuous in $t$ and $f: \mathbb{R} \rightarrow \mathbb{R}$ is $T$-periodic and continuous in $t$. Then the equation

$$
\begin{equation*}
x^{\prime}(t)+g(t, x(t))=f(t), \quad t \in \mathbb{R} \tag{27}
\end{equation*}
$$

has periodic solutions if and only if there is $x_{0} \in \mathbb{R}$ such that

$$
\begin{equation*}
\langle f\rangle:=\frac{1}{T} \int_{0}^{T} f(t) d t=\frac{1}{T} \int_{0}^{T} g\left(t, x_{0}\right) d t=G\left(x_{0}\right) \tag{28}
\end{equation*}
$$

Moreover, in this case we have the estimate

$$
\|x\|_{L^{\infty}(\mathbb{R})} \leq\left|x_{0}\right|+\int_{0}^{T}\left|f(t)-g\left(t, x_{0}\right)\right| d t, \quad \forall x_{0} \in G^{-1}\langle f\rangle
$$

Proof Consider the average function $G: \mathbb{R} \rightarrow \mathbb{R}$ given by

$$
G(x)=\frac{1}{T} \int_{0}^{T} g(t, x) d t, x \in \mathbb{R}
$$

It is easy to check that $G$ is also increasing and Lipschitz continuous with the same constant. Let us prove that the condition (28) is necessary. Suppose that $x$ is a periodic solution for (27). By integration on $[0, T]$ we get

$$
\begin{equation*}
\frac{1}{T} \int_{0}^{T} g(t, x(t)) d t=\langle f\rangle \tag{29}
\end{equation*}
$$

We can write

$$
m \leq x(t) \leq M, t \in[0, T]
$$

and thus

$$
g(t, m) \leq g(t, x(t)) \leq g(t, M), t \in[0, T]
$$

which implies

$$
G(m)=\frac{1}{T} \int_{0}^{T} g(t, m) d t \leq \frac{1}{T} \int_{0}^{T} g(t, x(t)) d t \leq \frac{1}{T} \int_{0}^{T} g(t, M) d t=G(M)
$$

Since $G$ is continuous it follows that there is $x_{0} \in[m, M]$ such that $G\left(x_{0}\right)=$ $\frac{1}{T} \int_{0}^{T} g(t, x(t)) d t$ and from (29) we deduce that $\langle f\rangle=G\left(x_{0}\right)$.
Let us show that the condition (28) is also sufficient. As before let us consider the unique periodic solution for

$$
\alpha x_{\alpha}(t)+x_{\alpha}^{\prime}(t)+g\left(t, x_{\alpha}(t)\right)=f(t), \quad t \in[0, T], \alpha>0
$$

(existence and uniqueness follow by the Banach's fixed point theorem exactly as before). All we need to prove is that $\left(x_{\alpha}\right)_{\alpha>0}$ is uniformly bounded in $L^{\infty}(\mathbb{R})$ (then $\left(x_{\alpha}^{\prime}\right)_{\alpha>0}$ is also uniformly bounded in $L^{\infty}(\mathbb{R})$ and by Arzela-Ascoli's theorem we deduce that $x_{\alpha}$ converges to a periodic solution for (27)). Taking the average on $[0, T]$ we get

$$
\frac{1}{T} \int_{0}^{T}\left\{\alpha x_{\alpha}(t)+g\left(t, x_{\alpha}(t)\right)\right\} d t=\langle f\rangle=G\left(x_{0}\right), \quad \alpha>0
$$

As before we can write

$$
\alpha m_{\alpha}+g\left(t, m_{\alpha}\right) \leq \alpha x_{\alpha}(t)+g\left(t, x_{\alpha}(t)\right) \leq \alpha M_{\alpha}+g\left(t, M_{\alpha}\right), \quad t \in[0, T], \alpha>0,
$$

where

$$
m_{\alpha} \leq x_{\alpha}(t) \leq M_{\alpha}, \quad t \in[0, T], \alpha>0,
$$

and hence

$$
\alpha m_{\alpha}+G\left(m_{\alpha}\right) \leq \frac{1}{T} \int_{0}^{T}\left\{\alpha x_{\alpha}(t)+g\left(t, x_{\alpha}(t)\right)\right\} d t \leq \alpha M_{\alpha}+G\left(M_{\alpha}\right), \quad \alpha>0
$$

Finally we get
$\left.G\left(x_{0}\right)=\frac{1}{T} \int_{0}^{T}\left\{\alpha x_{\alpha}(t)+g\left(t, x_{\alpha}(t)\right)\right\} d t=\alpha u_{\alpha}+G\left(u_{\alpha}\right), \quad u_{\alpha} \in\right] m_{\alpha}, M_{\alpha}[, \alpha>0$.
Multiplying by $u_{\alpha}-x_{0}$ we obtain

$$
\alpha u_{\alpha}\left(u_{\alpha}-x_{0}\right)=-\left(G\left(x_{0}\right)-G\left(u_{\alpha}\right)\right)\left(x_{0}-u_{\alpha}\right), \quad \alpha>0 .
$$

Since $G$ is increasing we deduce that $\left|u_{\alpha}\right|^{2} \leq u_{\alpha} x_{0} \leq\left|u_{\alpha}\right| \cdot\left|x_{0}\right|, \alpha>0$ and hence $\left(u_{\alpha}\right)_{\alpha>0}$ is bounded:

$$
\left|u_{\alpha}\right| \leq\left|x_{0}\right|, \quad \alpha>0 .
$$

Now using (30) it follows

$$
\frac{1}{T} \int_{0}^{T}\left\{\alpha x_{\alpha}(t)+g\left(t, x_{\alpha}(t)\right)\right\} d t=\frac{1}{T} \int_{0}^{T}\left\{\alpha u_{\alpha}+g\left(t, u_{\alpha}\right)\right\} d t,
$$

and thus there is $\left.t_{\alpha} \in\right] 0, T[$ such that

$$
\alpha x_{\alpha}\left(t_{\alpha}\right)+g\left(t_{\alpha}, x_{\alpha}\left(t_{\alpha}\right)\right)=\alpha u_{\alpha}+g\left(t_{\alpha}, u_{\alpha}\right), \quad \alpha>0 .
$$

Since $\alpha\left(x_{\alpha}\left(t_{\alpha}\right)-u_{\alpha}\right)^{2}=-\left[g\left(t_{\alpha}, x_{\alpha}\left(t_{\alpha}\right)\right)-g\left(t_{\alpha}, u_{\alpha}\right)\right]\left[x_{\alpha}\left(t_{\alpha}\right)-u_{\alpha}\right] \leq 0$ we find that $x_{\alpha}\left(t_{\alpha}\right)=u_{\alpha}, \alpha>0$ and thus $\left(x_{\alpha}\left(t_{\alpha}\right)\right)_{\alpha>0}$ is also bounded

$$
\left|x_{\alpha}\left(t_{\alpha}\right)\right| \leq\left|x_{0}\right|, \quad \alpha>0 .
$$

Now by standard calculations we can write

$$
\begin{aligned}
& \frac{1}{2} \frac{d}{d t}\left|x_{\alpha}(t)-x_{\alpha}\left(t_{\alpha}\right)\right|^{2}+\left[g\left(t, x_{\alpha}(t)\right)-g\left(t, x_{\alpha}\left(t_{\alpha}\right)\right)\right]\left[x_{\alpha}(t)-x_{\alpha}\left(t_{\alpha}\right)\right] \\
& \quad \leq \quad\left[f(t)-\alpha x_{\alpha}\left(t_{\alpha}\right)-g\left(t, x_{\alpha}\left(t_{\alpha}\right)\right)\right]\left[x_{\alpha}(t)-x_{\alpha}\left(t_{\alpha}\right)\right], \quad t \in \mathbb{R},
\end{aligned}
$$

and thus

$$
\left|x_{\alpha}(t)-x_{\alpha}\left(t_{\alpha}\right)\right| \leq \int_{t_{\alpha}}^{t}\left|f(s)-\alpha x_{\alpha}\left(t_{\alpha}\right)-g\left(s, x_{\alpha}\left(t_{\alpha}\right)\right)\right| d s, \quad t>t_{\alpha}, \alpha>0
$$

which implies

$$
\begin{equation*}
\left|x_{\alpha}(t)\right| \leq\left|x_{0}\right|+\int_{0}^{T}\left|f(t)-\alpha x_{\alpha}\left(t_{\alpha}\right)-g\left(t, x_{\alpha}\left(t_{\alpha}\right)\right)\right| d t, \quad t \in[0, T], \alpha>0 . \tag{31}
\end{equation*}
$$

Since $\left(x_{\alpha}\left(t_{\alpha}\right)\right)_{\alpha>0}$ is bounded we have

$$
u_{\alpha}=x_{\alpha}\left(t_{\alpha}\right) \rightarrow x_{1},
$$

such that

$$
G\left(x_{0}\right)=\lim _{\alpha \rightarrow 0}\left\{\alpha u_{\alpha}+G\left(u_{\alpha}\right)\right\}=G\left(x_{1}\right) .
$$

Moreover, if $x_{0} \leq x_{1}$ we have

$$
0 \leq \frac{1}{T} \int_{0}^{T}\left[g\left(t, x_{1}\right)-g\left(t, x_{0}\right)\right] d t=G\left(x_{1}\right)-G\left(x_{0}\right)=0
$$

and hence $g\left(t, x_{1}\right)=g\left(t, x_{0}\right)$ for all $t \in[0, T]$. Obviously the same equalities hold if $x_{0}>x_{1}$. Now by passing to the limit in (31) we find

$$
\begin{align*}
|x(t)| & \leq\left|x_{0}\right|+\int_{0}^{T}\left|f(t)-g\left(t, x_{1}\right)\right| d t  \tag{32}\\
& =\left|x_{0}\right|+\int_{0}^{T}\left|f(t)-g\left(t, x_{0}\right)\right| d t, \quad t \in[0, T], \forall x_{0} \in G^{-1}\langle f\rangle,
\end{align*}
$$

and therefore $\left(x_{\alpha}\right)_{\alpha>0}$ is uniformly bounded in $L^{\infty}(\mathbb{R})$.

## 3 Periodic solutions for evolution equations on Hilbert spaces

In this section we analyze the existence and uniqueness of periodic solutions for general evolution equations on Hilbert spaces

$$
\begin{equation*}
x^{\prime}(t)+A x(t)=f(t), \quad t>0 \tag{33}
\end{equation*}
$$

where $A: D(A) \subset H \rightarrow H$ is a maximal monotone operator on a Hilbert space $H$ and $f \in C^{1}(\mathbb{R} ; H)$ is a $T$-periodic function. As known by the theory of Hille-Yosida, for every initial data $x_{0} \in D(A)$ there is an unique solution $x \in C^{1}([0,+\infty[; H) \cap C([0,+\infty[; D(A))$ for (33), see [6, p. 101]. Obviously, the periodic problem reduces to find $x_{0} \in D(A)$ such that $x(T)=x_{0}$. As in the one dimensional case we demonstrate uniqueness for strictly monotone operators. We state also necessary and sufficient condition for the existence in the linear symmetric case. Finally the case of non-linear sub-differential operators is considered. Let us start with the definition of periodic solutions for (33).

Definition 3.1 Let $A: D(A) \subset H \rightarrow H$ be a maximal monotone operator on a Hilbert space $H$ and $f \in C^{1}(\mathbb{R} ; H)$ a T-periodic function. We say that $x \in C^{1}([0, T] ; H) \cap C([0, T] ; D(A))$ is a periodic solution for (33) if and only if

$$
x^{\prime}(t)+A x(t)=f(t), \quad t \in[0, T],
$$

and $x(0)=x(T)$.

### 3.1 Uniqueness

Generally the uniqueness does not hold (see the example in the following paragraph). However it occurs under the hypothesis of strictly monotony

Proposition 3.2 Assume that $A$ is strictly monotone $\left(\left(A x_{1}-A x_{2}, x_{1}-x_{2}\right)=0\right.$ implies $x_{1}=x_{2}$ ). Then (33) has at most one periodic solution.

Proof Let $x_{1}, x_{2}$ be two different periodic solutions. By taking the difference of (33) and multiplying both sides by $x_{1}(t)-x_{2}(t)$ we find

$$
\frac{1}{2} \frac{d}{d t}\left\|x_{1}(t)-x_{2}(t)\right\|^{2}+\left(A x_{1}(t)-A x_{2}(t), \quad x_{1}(t)-x_{2}(t)\right)=0, \quad t \in[0, T] .
$$

By the monotony of $A$ we deduce that $\left\|x_{1}-x_{2}\right\|^{2}$ is decreasing and therefore we have

$$
\left\|x_{1}(0)-x_{2}(0)\right\| \geq\left\|x_{1}(t)-x_{2}(t)\right\| \geq\left\|x_{1}(T)-x_{2}(T)\right\|, \quad t \in[0, T] .
$$

Since $x_{1}$ and $x_{2}$ are $T$-periodic we have

$$
\left\|x_{1}(0)-x_{2}(0)\right\|=\left\|x_{1}(T)-x_{2}(T)\right\|,
$$

which implies that $\left\|x_{1}(t)-x_{2}(t)\right\|$ is constant for $t \in[0, T]$ and thus

$$
\left(A x_{1}(t)-A x_{2}(t), \quad x_{1}(t)-x_{2}(t)\right)=0, \quad t \in[0, T] .
$$

Now uniqueness follows by the strictly monotony of $A$.

### 3.2 Existence

In this section we establish existence results. In the linear case we state the following necessary condition.

Proposition 3.3 Let $A: D(A) \subset H \rightarrow H$ be a linear maximal monotone operator and $f \in L^{1}(] 0, T[; H)$ a T-periodic function. If (33) has T-periodic solutions, then the following necessary condition holds.

$$
\langle f\rangle:=\frac{1}{T} \int_{0}^{T} f(t) d t \in \operatorname{Range}(A)
$$

(there is $x_{0} \in D(A)$ such that $\langle f\rangle=A x_{0}$ ).

Proof Suppose that $x \in C^{1}([0, T] ; H) \cap C([0, T] ; D(A))$ is a $T$-periodic solution for (33). Let us consider the divisions $\Delta_{n}: 0=t_{0}^{n}<t_{1}^{n}<\cdots<t_{n}^{n}=T$ such that

$$
\begin{equation*}
\lim _{n \rightarrow \infty} \max _{1 \leq i \leq n}\left|t_{i}^{n}-t_{i-1}^{n}\right|=0 \tag{34}
\end{equation*}
$$

We can write

$$
\left(t_{i}^{n}-t_{i-1}^{n}\right) x^{\prime}\left(t_{i-1}^{n}\right)+\left(t_{i}^{n}-t_{i-1}^{n}\right) A x\left(t_{i-1}^{n}\right)=\left(t_{i}^{n}-t_{i-1}^{n}\right) f\left(t_{i-1}^{n}\right), \quad 1 \leq i \leq n
$$

Since $A$ is linear we deduce
$\frac{1}{T} \sum_{i=1}^{n}\left(t_{i}^{n}-t_{i-1}^{n}\right) x^{\prime}\left(t_{i-1}^{n}\right)+A\left(\frac{1}{T} \sum_{i=1}^{n}\left(t_{i}^{n}-t_{i-1}^{n}\right) x\left(t_{i-1}^{n}\right)\right)=\frac{1}{T} \sum_{i=1}^{n}\left(t_{i}^{n}-t_{i-1}^{n}\right) f\left(t_{i-1}^{n}\right)$,
and hence

$$
\left.\left[\frac{1}{T} \sum_{i=1}^{n}\left(t_{i}^{n}-t_{i-1}^{n}\right) x\left(t_{i-1}^{n}\right)\right), \frac{1}{T} \sum_{i=1}^{n}\left(t_{i}^{n}-t_{i-1}^{n}\right)\left[f\left(t_{i-1}^{n}\right)-x^{\prime}\left(t_{i-1}^{n}\right)\right]\right] \in A .
$$

By (34) we deduce that

$$
\left.\frac{1}{T} \sum_{i=1}^{n}\left(t_{i}^{n}-t_{i-1}^{n}\right) x\left(t_{i-1}^{n}\right)\right) \rightarrow \frac{1}{T} \int_{0}^{T} x(t) d t
$$

and

$$
\begin{aligned}
\frac{1}{T} \sum_{i=1}^{n}\left(t_{i}^{n}-t_{i-1}^{n}\right)\left[f\left(t_{i-1}^{n}\right)-x^{\prime}\left(t_{i-1}^{n}\right)\right] & \rightarrow \frac{1}{T} \int_{0}^{T}\left[f(t)-x^{\prime}(t)\right] d t \\
& =\frac{1}{T} \int_{0}^{T} f(t) d t-\left.\frac{1}{T} x(t)\right|_{0} ^{T} \\
& =\frac{1}{T} \int_{0}^{T} f(t) d t
\end{aligned}
$$

Since $A$ is maximal monotone $\operatorname{Graph}(A)$ is closed and therefore

$$
\left[\frac{1}{T} \int_{0}^{T} x(t) d t, \frac{1}{T} \int_{0}^{T} f(t) d t\right] \in A
$$

Thus $\frac{1}{T} \int_{0}^{T} x(t) d t \in D(A)$ and $\langle f\rangle=A\left(\frac{1}{T} \int_{0}^{T} x(t) d t\right)$. Generally the previous condition is not sufficient for the existence of periodic solutions. For example let us analyse the periodic solutions $x=\left(x_{1}, x_{2}\right) \in C^{1}\left([0, T] ; \mathbb{R}^{2}\right)$ for

$$
\begin{equation*}
x^{\prime}(t)+A x(t)=f(t), t \in[0, T] \tag{35}
\end{equation*}
$$

where $A: \mathbb{R}^{2} \rightarrow \mathbb{R}^{2}$ is the orthogonal rotation:

$$
A\left(x_{1}, x_{2}\right)=\left(-x_{2}, x_{1}\right),\left(x_{1}, x_{2}\right) \in \mathbb{R}^{2}
$$

and $f=\left(f_{1}, f_{2}\right) \in L^{1}(] 0, T\left[; \mathbb{R}^{2}\right)$ is $T$-periodic. For a given initial data $x(0)=$ $x_{0} \in \mathbb{R}^{2}$ the solution writes

$$
\begin{equation*}
x(t)=e^{-t A} x_{0}+\int_{0}^{t} e^{-(t-s) A} f(s) d s, \quad t>0 \tag{36}
\end{equation*}
$$

where the semigroup $e^{-t A}$ is given by

$$
e^{-t A}=\left(\begin{array}{cc}
\cos t & \sin t  \tag{37}\\
-\sin t & \cos t
\end{array}\right)
$$

Since $e^{-2 \pi A}=1$ we deduce that the equation (35) has $2 \pi$-periodic solutions if and only if

$$
\begin{equation*}
\int_{0}^{2 \pi} e^{t A} f(t) d t=0 \tag{38}
\end{equation*}
$$

Thus if $\int_{0}^{2 \pi}\left\{f_{1}(t) \cos t-f_{2}(t) \sin t\right\} d t \neq 0$ or $\int_{0}^{2 \pi}\left\{f_{1}(t) \sin t+f_{2}(t) \cos t\right\} d t \neq 0$ equation (35) does not have any $2 \pi$-periodic solution and the necessary condition still holds because $\operatorname{Range}(A)=\mathbb{R}^{2}$. Moreover if (38) is satisfied then every solution of (35) is periodic and therefore uniqueness does not occur (the operator $A$ is not strictly monotone). Let us analyse now the existence. As in the one dimensional case we have

Proposition 3.4 Suppose that $A: D(A) \subset H \rightarrow H$ is maximal monotone and $f \in C^{1}(\mathbb{R} ; H)$ is $T$-periodic. Then for every $\alpha>0$ the equation

$$
\begin{equation*}
\alpha x(t)+x^{\prime}(t)+A x(t)=f(t), \quad t \in \mathbb{R}, \tag{39}
\end{equation*}
$$

has an unique $T$-periodic solution in $C^{1}(\mathbb{R} ; H) \cap C(\mathbb{R} ; D(A))$.
Proof Since $\alpha+A$ is strictly monotone the uniqueness follows from Proposition 3.2. Indeed,

$$
\alpha\|x-y\|^{2}+(A x-A y, x-y)=0, \quad x, y \in D(A)
$$

implies $\alpha\|x-y\|^{2}=0$ and hence $x=y$.
Consider now an arbitrary initial data $x_{0} \in D(A)$. By the Hille-Yosida's theorem, there is $x \in C^{1}([0,+\infty[; H) \cap C([0,+\infty[; D(A))$ solution for (39). Denote by $\left(x_{n}\right)_{n \geq 0}$ the functions

$$
x_{n}(t)=x(n T+t), \quad t \in[0, T], n \geq 0 .
$$

We have

$$
\alpha x_{n+1}(t)+x_{n+1}^{\prime}(t)+A x_{n+1}(t)=f((n+1) T+t), \quad t \in[0, T]
$$

and

$$
\alpha x_{n}(t)+x_{n}^{\prime}(t)+A x_{n}(t)=f(n T+t), \quad t \in[0, T] .
$$

Since $f$ is $T$-periodic, after usual computations we get

$$
\begin{aligned}
& \alpha\left\|x_{n+1}(t)-x_{n}(t)\right\|^{2}+\frac{1}{2} \frac{d}{d t}\left\|x_{n+1}(t)-x_{n}(t)\right\|^{2} \\
& \quad+\left(A x_{n+1}(t)-A x_{n}(t), x_{n+1}(t)-x_{n}(t)\right) \quad=\quad 0, \quad t \in[0, T] .
\end{aligned}
$$

Taking into account that $A$ is monotone we deduce

$$
\left\|x_{n+1}(t)-x_{n}(t)\right\| \leq e^{-\alpha t}\left\|x_{n+1}(0)-x_{n}(0)\right\|, \quad t \in[0, T]
$$

and hence

$$
\begin{align*}
\left\|x_{n+1}(0)-x_{n}(0)\right\| & =\left\|x_{n}(T)-x_{n-1}(T)\right\| \\
& \leq e^{-\alpha T}\left\|x_{n}(0)-x_{n-1}(0)\right\| \\
& \leq e^{-2 \alpha T}\left\|x_{n-1}(0)-x_{n-2}(0)\right\| \\
& \leq \cdots \\
& \leq e^{-n \alpha T}\left\|x_{1}(0)-x_{0}(0)\right\|, \quad n \geq 0 . \tag{40}
\end{align*}
$$

Finally we get the estimate

$$
\left\|x_{n+1}(t)-x_{n}(t)\right\| \leq e^{-\alpha(n T+t)}\left\|S_{\alpha}\left(T ; 0, x_{0}\right)-x_{0}\right\|, \quad t \in[0, T], n \geq 0
$$

Here $S_{\alpha}\left(t ; 0, x_{0}\right)$ represents the solution of (39) for the initial data $x_{0}$. From the previous estimate it is clear that $\left(x_{n}\right)_{n \geq 0}$ is convergent in $C^{0}([0, T] ; H)$ :

$$
x_{n}(t)=x_{0}(t)+\sum_{k=0}^{n-1}\left(x_{k+1}(t)-x_{k}(t)\right), \quad t \in[0, T]
$$

where

$$
\begin{aligned}
\left\|\sum_{k=0}^{n-1}\left(x_{k+1}(t)-x_{k}(t)\right)\right\| & \leq \sum_{k=0}^{n-1}\left\|x_{k+1}(t)-x_{k}(t)\right\| \\
& \leq \sum_{k=0}^{n-1} e^{-\alpha(k T+t)}\left\|S_{\alpha}\left(T ; 0, x_{0}\right)-x_{0}\right\| \\
& \leq \frac{e^{-\alpha t}}{1-e^{-\alpha T}}\left\|S_{\alpha}\left(T ; 0, x_{0}\right)-x_{0}\right\|
\end{aligned}
$$

Moreover $\left\|x_{n}(t)\right\| \leq\left\|S_{\alpha}\left(t ; 0, x_{0}\right)\right\|+\frac{1}{1-e^{-\alpha T}}\left\|S_{\alpha}\left(T ; 0, x_{0}\right)-x_{0}\right\|$. Denote by $x_{\alpha}$ the limit of $\left(x_{n}\right)_{n \geq 0}$ as $n \rightarrow \infty$. We should note that without any other hypothesis $\left(x_{\alpha}\right)_{\alpha>0}$ is not uniformly bounded in $L^{\infty}(] 0, T[; H)$. We have only estimate in $\mathcal{O}\left(1+\frac{1}{\alpha}\right)$,

$$
\left\|x_{\alpha}\right\|_{L^{\infty}([0, T] ; H)} \leq C\left(1+\frac{1}{1-e^{-\alpha T}}\right) \sim \mathcal{O}\left(1+\frac{1}{\alpha}\right)
$$

The above estimate leads immediately to the following statement.

Remark 3.5 The sequence $\left(\alpha x_{\alpha}\right)_{\alpha>0}$ is uniformly bounded in $L^{\infty}([0, T] ; H)$.
Let us demonstrate that $x_{\alpha}$ is $T$-periodic and solution for (39). Indeed,

$$
x_{\alpha}(0)=\lim _{n \rightarrow \infty} x_{n}(0)=\lim _{n \rightarrow \infty} x_{n-1}(T)=x_{\alpha}(T)
$$

Now let us show that $\left(x_{n}^{\prime}\right)_{n \geq 0}$ is also uniformly bounded in $L^{\infty}(] 0, T[; H)$. By taking the difference between the equations (39) at the moments $t$ and $t+h$ we have
$\alpha(x(t+h)-x(t))+x^{\prime}(t+h)-x^{\prime}(t)+A x(t+h)-A x(t)=f(t+h)-f(t), \quad t<t+h$.
Multiplying by $x(t+h)-x(t)$ we obtain
$\alpha\|x(t+h)-x(t)\|^{2}+\frac{1}{2} \frac{d}{d t}\|x(t+h)-x(t)\|^{2} \leq\|f(t+h)-f(t)\| \cdot\|x(t+h)-x(t)\|$,
which can be also rewritten as

$$
\begin{aligned}
\frac{1}{2} e^{2 \alpha t}\|x(t+h)-x(t)\|^{2} \leq & \int_{0}^{t} e^{\alpha s}\|f(s+h)-f(s)\| \cdot e^{\alpha s}\|x(s+h)-x(s)\| d s \\
& +\frac{1}{2}\|x(h)-x(0)\|^{2}, \quad t<t+h
\end{aligned}
$$

By using Bellman's lemma we conclude that

$$
\begin{align*}
\frac{1}{h}\|x(t+h)-x(t)\| \leq & \int_{0}^{t} e^{-\alpha(t-s)} \frac{1}{h}\|f(s+h)-f(s)\| d s \\
& +e^{-\alpha t} \frac{1}{h}\|x(h)-x(0)\|, \quad 0 \leq t<t+h \tag{41}
\end{align*}
$$

By passing to the limit for $h \rightarrow 0$ the previous formula yields

$$
\begin{aligned}
\left\|x^{\prime}(t)\right\| & \leq e^{-\alpha t}\left\|x^{\prime}(0)\right\|+\int_{0}^{t} e^{-\alpha(t-s)}\left\|f^{\prime}(s)\right\| d s \\
& \leq e^{-\alpha t}\left\|f(0)-\alpha x_{0}-A x_{0}\right\|+\frac{1}{\alpha}\left(1-e^{-\alpha t}\right)\left\|f^{\prime}\right\|_{L^{\infty}(] 0, T[; H)} \\
& \leq\left\|f(0)-\alpha x_{0}-A x_{0}\right\|+\frac{1}{\alpha}\left\|f^{\prime}\right\|_{L^{\infty}(] 0, T[; H)}<+\infty
\end{aligned}
$$

Therefore $\left(x_{n}^{\prime}\right)_{n \geq 0}$ is uniformly bounded in $L^{\infty}(] 0, T[; H)$ since

$$
\left\|x_{n}^{\prime}\right\|_{L^{\infty}(] 0, T[; H)}=\left\|x^{\prime}(n T+(\cdot))\right\|_{L^{\infty}(] 0, T[; H)} \leq\left\|x^{\prime}\right\|_{L^{\infty}([0,+\infty[; H)}
$$

and thus we have $x_{n}^{\prime}(t) \rightharpoonup y_{\alpha}(t), t \in[0, T]$. We can write

$$
\left(x_{n}(t), z\right)=\left(x_{n}(0), z\right)+\int_{0}^{t}\left(x_{n}^{\prime}(s), z\right) d s, \quad z \in H, t \in[0, T], n \geq 0
$$

and by passing to the limit for $n \rightarrow \infty$ we deduce

$$
\left(x_{\alpha}(t), z\right)=\left(x_{\alpha}(0), z\right)+\int_{0}^{t}\left(y_{\alpha}(s), z\right) d s, \quad z \in H, t \in[0, T]
$$

which is equivalent to

$$
x_{\alpha}(t)=x_{\alpha}(0)+\int_{0}^{t} y_{\alpha}(s) d s, \quad t \in[0, T] .
$$

Therefore $x_{\alpha}$ is differentiable and $x_{\alpha}^{\prime}=y_{\alpha}$. Finally we can write $x_{n}^{\prime}(t) \rightharpoonup x_{\alpha}^{\prime}(t)$, $t \in[0, T]$. Let us show that $x_{\alpha}$ is also solution for (39). We have

$$
\left[x_{n}(t), f(t)-\alpha x_{n}(t)-x_{n}^{\prime}(t)\right] \in A, \quad n \geq 0, t \in[0, T]
$$

Since $x_{n}(t) \rightarrow x_{\alpha}(t), x_{n}^{\prime}(t) \rightharpoonup x_{\alpha}^{\prime}(t)$ and $A$ is maximal monotone we conclude that

$$
\left[x_{\alpha}(t), f(t)-x_{\alpha}^{\prime}(t)\right] \in A, \quad t \in[0, T], \alpha>0
$$

which means that $x_{\alpha}(t) \in D(A)$ and $A x_{\alpha}(t)=f(t)-x_{\alpha}^{\prime}(t), \quad t \in[0, T]$.
Now we establish for the linear case the similar result stated in Proposition 2.10. Before let us recall a standard result concerning maximal monotone operators on Hilbert spaces

Proposition 3.6 Assume that $A$ is a maximal monotone operator (linear or not) and $\alpha u_{\alpha}+A u_{\alpha}=f, u_{\alpha} \in D(A), f \in H, \alpha>0$. Then the following statements are equivalent:
(i) $f \in \operatorname{Range}(A)$;
(ii) $\left(u_{\alpha}\right)_{\alpha>0}$ is bounded in H. Moreover, in this case $\left(u_{\alpha}\right)_{\alpha>0}$ is convergent in $H$ to the element of minimal norm in $A^{-1} f$.

Proof it (i) $\rightarrow$ (ii) By the hypothesis there is $u \in D(A)$ such that $f=A u$. After multiplication by $u_{\alpha}-u$ we get

$$
\alpha\left(u_{\alpha}, u_{\alpha}-u\right)+\left(A u_{\alpha}-A u, u_{\alpha}-u\right)=0, \quad \alpha>0 .
$$

Taking into account that $A$ is monotone we deduce

$$
\left\|u_{\alpha}\right\|^{2} \leq\left(u_{\alpha}, u\right) \leq\left\|u_{\alpha}\right\| \cdot\|u\|, \quad \alpha>0
$$

and hence $\left\|u_{\alpha}\right\| \leq\|u\|, \alpha>0, u \in A^{-1} f$ which implies that $u_{\alpha} \rightharpoonup u_{0}$. We have $\left[u_{\alpha}, f-\alpha u_{\alpha}\right] \in A, \alpha>0$ and since $A$ is maximal monotone, by passing to the limit for $\alpha \rightarrow 0$ we deduce that $\left[u_{0}, f\right] \in A$, or $u_{0} \in A^{-1} f$. Moreover

$$
\left\|u_{0}\right\|=\left\|w-\lim _{\alpha \rightarrow 0} u_{\alpha}\right\| \leq \liminf _{\alpha \rightarrow 0}\left\|u_{\alpha}\right\| \leq \limsup _{\alpha \rightarrow 0}\left\|u_{\alpha}\right\| \leq\|u\|, \quad \forall u \in A^{-1} f
$$

In particulat taking $u=u_{0} \in A^{-1} f$ we get

$$
\left\|w-\lim _{\alpha \rightarrow 0} u_{\alpha}\right\|=\lim _{\alpha \rightarrow 0}\left\|u_{\alpha}\right\|
$$

and hence, since any Hilbert space is strictly convex, by Mazur's theorem we deduce that the convergence is strong

$$
u_{\alpha} \rightarrow u_{0} \in A^{-1} f, \quad \alpha \rightarrow 0
$$

where $\left\|u_{0}\right\|=\inf _{u \in A^{-1} f}\|u\|=\min _{u \in A^{-1} f}\|u\|$.
(ii) $\rightarrow$ (i) Conversely, suppose that $\left(u_{\alpha}\right)_{\alpha>0}$ is bounded in $H$. Therefore $u_{\alpha} \rightharpoonup u$ in $H$. We have $\left[u_{\alpha}, f-\alpha u_{\alpha}\right] \in A, \alpha>0$ and since $A$ is maximal monotone by passing to the limit for $\alpha \rightarrow 0$ we deduce that $[u, f] \in A$ or $u \in D(A)$ and $f=A u$.

Theorem 3.7 Assume that $A: D(A) \subset H \rightarrow H$ is a linear maximal monotone operator on a compact Hilbert space $H$ and $f \in C^{1}(\mathbb{R} ; H)$ is a T-periodic function. Then the following statements are equivalent:
(i) equation (33) has periodic solutions;
(ii) the sequence of periodic solutions for (39) is bounded in $C^{1}(\mathbb{R} ; H)$. Moreover in this case $\left(x_{\alpha}\right)_{\alpha>0}$ is convergent in $C^{0}(\mathbb{R} ; H)$ and the limit is also a $T$-periodic solution for (33).

Proof (i) $\rightarrow$ (ii) Denote by $x, x_{\alpha}$ the periodic solutions for (33) and (39). By taking the difference and after multiplication by $x_{\alpha}(t)-x(t)$ we get:

$$
\begin{equation*}
\alpha\left\|x_{\alpha}(t)-x(t)\right\|^{2}+\frac{1}{2} \frac{d}{d t}\left\|x_{\alpha}(t)-x(t)\right\|^{2} \leq \alpha\|x(t)\| \cdot\left\|x_{\alpha}(t)-x(t)\right\|, \quad t \in \mathbb{R} \tag{42}
\end{equation*}
$$

Finally, after integration and by using Bellman's lemma, formula (42) yields

$$
\begin{aligned}
\left\|x_{\alpha}(t)-x(t)\right\| & \leq e^{-\alpha t}\left\|x_{\alpha}(0)-x(0)\right\|+\int_{0}^{t} \alpha e^{-\alpha(t-s)}\|x(s)\| d s \\
& \leq e^{-\alpha t}\left\|x_{\alpha}(0)-x(0)\right\|+\left(1-e^{-\alpha t}\right)\|x\|_{L^{\infty}}, \quad t \in \mathbb{R}
\end{aligned}
$$

Since $x_{\alpha}$ and $x$ are $T$-periodic we can also write

$$
\begin{aligned}
\left\|x_{\alpha}(t)-x(t)\right\| & =\left\|x_{\alpha}(n T+t)-x(n T+t)\right\| \\
& \leq e^{-\alpha(n T+t)}\left\|x_{\alpha}(0)-x(0)\right\|+\left(1-e^{-\alpha(n T+t)}\right)\|x\|_{L^{\infty}} .
\end{aligned}
$$

By passing to the limit for $n \rightarrow \infty$ we obtain

$$
\left\|x_{\alpha}-x\right\|_{L^{\infty}} \leq\|x\|_{L^{\infty}}, \quad \alpha>0
$$

and hence

$$
\left\|x_{\alpha}\right\|_{L^{\infty}} \leq 2\|x\|_{L^{\infty}}, \quad \alpha>0 .
$$

Since $A$ is linear we can write

$$
\begin{aligned}
& \frac{\alpha}{h}\left(x_{\alpha}(t+h)-x_{\alpha}(t)\right)+\frac{1}{h}\left(x_{\alpha}^{\prime}(t+h)-x_{\alpha}^{\prime}(t)\right)+\frac{1}{h} A\left(x_{\alpha}(t+h)-x_{\alpha}(t)\right) \\
& \quad=\frac{1}{h}(f(t+h)-f(t)), \quad t<t+h, \alpha>0
\end{aligned}
$$

and for $t<t+h$,

$$
\frac{1}{h}\left(x^{\prime}(t+h)-x^{\prime}(t)\right)+\frac{1}{h} A(x(t+h)-x(t))=\frac{1}{h}(f(t+h)-f(t))
$$

For every $h>0$ denote by $y_{\alpha, h}, y_{h}$ and $g_{h}$ the periodic functions:

$$
\begin{gathered}
y_{\alpha, h}(t)=\frac{1}{h}\left(x_{\alpha}(t+h)-x_{\alpha}(t)\right), \quad t \in \mathbb{R}, \alpha>0 \\
y_{h}(t)=\frac{1}{h}(x(t+h)-x(t)), \quad t \in \mathbb{R} \\
g_{h}(t)=\frac{1}{h}(f(t+h)-f(t)), \quad t \in \mathbb{R},
\end{gathered}
$$

and hence we have

$$
\begin{gathered}
\alpha y_{\alpha, h}(t)+y_{\alpha, h}^{\prime}(t)+A y_{\alpha, h}(t)=g_{h}(t), \quad t \in \mathbb{R} \\
y_{h}^{\prime}(t)+A y_{h}(t)=g_{h}(t), \quad t \in \mathbb{R}
\end{gathered}
$$

By the same computations we get

$$
\left\|y_{\alpha, h}(t)-y_{h}(t)\right\| \leq e^{-\alpha t}\left\|y_{\alpha, h}(0)-y_{h}(0)\right\|+\int_{0}^{t} \alpha e^{-\alpha(t-s)}\left\|y_{h}(s)\right\| d s
$$

Now by passing to the limit for $h \rightarrow 0$ we deduce

$$
\begin{aligned}
\left\|x_{\alpha}^{\prime}(t)-x^{\prime}(t)\right\| & \leq e^{-\alpha t}\left\|x_{\alpha}^{\prime}(0)-x^{\prime}(0)\right\|+\int_{0}^{t} \alpha e^{-\alpha(t-s)}\left\|x^{\prime}(s)\right\| d s \\
& \leq e^{-\alpha t}\left\|x_{\alpha}^{\prime}(0)-x^{\prime}(0)\right\|+\left(1-e^{-\alpha t}\right)\left\|x^{\prime}\right\|_{L^{\infty}}, \quad t \in[0, T]
\end{aligned}
$$

By the periodicity we obtain as before that

$$
\begin{aligned}
\left\|x_{\alpha}^{\prime}(t)-x^{\prime}(t)\right\| & =\left\|x_{\alpha}^{\prime}(n T+t)-x^{\prime}(n T+t)\right\| \\
& \leq e^{-\alpha(n T+t)}\left\|x_{\alpha}^{\prime}(0)-x^{\prime}(0)\right\|+\left(1-e^{-\alpha(n T+t)}\right)\left\|x^{\prime}\right\|_{L^{\infty}}
\end{aligned}
$$

and hence by passing to the limit for $n \rightarrow \infty$ we conclude that

$$
\left\|x_{\alpha}^{\prime}-x^{\prime}\right\|_{L^{\infty}} \leq\left\|x^{\prime}\right\|_{L^{\infty}}, \quad \alpha>0
$$

Therefore, $\left(x_{\alpha}^{\prime}\right)_{\alpha>0}$ is also uniformly bounded in $L^{\infty}$

$$
\left\|x_{\alpha}^{\prime}\right\|_{L^{\infty}} \leq 2\left\|x^{\prime}\right\|_{L^{\infty}}, \quad \alpha>0
$$

Conversely, the implication (ii) $\rightarrow$ (i) follows by using Arzela-Ascoli's theorem and by passing to the limit for $\alpha \rightarrow 0$ in (39).

Let us continue the analysis of the previous example. The semigroup associated to the equation (39) is given by

$$
e^{-t(\alpha+A)}=e^{-\alpha t} e^{-t A}=e^{-\alpha t}\left(\begin{array}{cc}
\cos t, & \sin t \\
-\sin t, & \cos t
\end{array}\right) \quad t \in \mathbb{R}, \alpha>0
$$

and the periodic solution for equation (39) reads

$$
\begin{aligned}
x_{\alpha}(t)= & \left(1-e^{-T(\alpha+A)}\right)^{-1} \int_{0}^{T} e^{-(T-s)(\alpha+A)} f(s) d s \\
& +\int_{0}^{t} e^{-(t-s)(\alpha+A)} f(s) d s \\
= & \frac{1-e^{-T(\alpha-A)}}{\left(1-e^{-\alpha T} \cos T\right)^{2}+\left(e^{-\alpha T} \sin T\right)^{2}} \int_{0}^{T} e^{-(T-s)(\alpha+A)} f(s) d s \\
& +\int_{0}^{t} e^{-(t-s)(\alpha+A)} f(s) d s, \quad t>0, \alpha>0 .
\end{aligned}
$$

As we have seen, proving the existence of periodic solutions reduces to finding uniform $L^{\infty}(] 0, T[; H)$ estimates for $\left(x_{\alpha}\right)_{\alpha>0}$ and $\left(x_{\alpha}^{\prime}\right)_{\alpha>0}$. Since $A$ is linear bounded operator $\left(\|A\|_{\mathcal{L}(H ; H)}=1\right)$ we have

$$
\begin{aligned}
\left\|x_{\alpha}^{\prime}\right\|_{L^{\infty}(] 0, T[; H)} & =\left\|f-\alpha x_{\alpha}-A x_{\alpha}\right\|_{L^{\infty}(] 0, T[; H)} \\
& \leq\|f\|_{L^{\infty}(] 0, T[; H)}+\left(\alpha+\|A\|_{\mathcal{L}(H ; H)}\right)\left\|x_{\alpha}\right\|_{L^{\infty}(\mathrm{j} 0, T[; H)}, \alpha>0
\end{aligned}
$$

and hence in this case it is sufficient to find only uniform $L^{\infty}(] 0, T[; H)$ estimates for $\left(x_{\alpha}\right)_{\alpha>0}$ or uniform estimates for $\left(x_{\alpha}(0)\right)_{\alpha>0}$ in $H$.
Case 1: $T=2 n \pi, n \geq 0$. We have

$$
\lim _{\alpha \rightarrow 0} x_{\alpha}(0)=\lim _{\alpha \rightarrow 0} \frac{1}{1-e^{-\alpha T}} \int_{0}^{T} e^{-(T-s)(\alpha+A)} f(s) d s
$$

If $\int_{0}^{T} e^{-(T-s) A} f(s) d s \neq 0$, then $\left(x_{\alpha}(0)\right)_{\alpha>0}$ is not bounded. In fact since $e^{-2 n \pi A}=1$ it is easy to check that equation (35) does not have any periodic solution. If $\int_{0}^{T} e^{-(T-s) A} f(s) d s=0$ then every solution of (35) is $T$-periodic and $\left(x_{\alpha}(0)\right)_{\alpha>0}$ is convergent for $\alpha \rightarrow 0$ :

$$
\begin{aligned}
\lim _{\alpha \rightarrow 0} x_{\alpha}(0) & =\lim _{\alpha \rightarrow 0} \frac{\int_{0}^{T}\left(e^{-\alpha(T-s)}-1\right) e^{-(T-s) A} f(s) d s}{1-e^{-\alpha T}} \\
& =-\int_{0}^{T} \frac{T-s}{T} e^{-(T-s) A} f(s) \\
& =\frac{1}{T} \int_{0}^{T} s e^{-(T-s) A} f(s)
\end{aligned}
$$

Case 2: $T \neq 2 n \pi$ for all $n \geq 0$. In this case $\left(1-e^{-T A}\right)$ is invertible and $\left(x_{\alpha}(0)\right)_{\alpha>0}$ converges to $x(0)$ where $x$ is the unique $T$-periodic solution of (35):

$$
\begin{aligned}
\lim _{\alpha \rightarrow 0} x_{\alpha}(0) & =\lim _{\alpha \rightarrow 0}\left(1-e^{-T(\alpha+A)}\right)^{-1} \int_{0}^{T} e^{-(T-s)(\alpha+A)} f(s) d s \\
& =\left(1-e^{-T A}\right)^{-1} \int_{0}^{T} e^{-(T-s) A} f(s) d s \\
& =\frac{1}{2 \sin \left(\frac{T}{2}\right)} \int_{0}^{T} e^{-\left(\frac{T+\pi}{2}-s\right) A} f(s) d s .
\end{aligned}
$$

We state now our main result of existence in the linear and symmetric case.
Theorem 3.8 Assume that $A: D(A) \subset H \rightarrow H$ is a linear maximal monotone and symmetric operator and $f \in C^{1}([0, T] ; H)$ is a T-periodic function. Then the necessary and sufficient condition for the existence of periodic solutions for (33) is given by

$$
\langle f\rangle:=\frac{1}{T} \int_{0}^{T} f(t) d t \in \operatorname{Range}(A)
$$

In this case we have the estimates:

$$
\|x\|_{L^{\infty}(] 0, T[; H)} \leq\left\|A^{-1}\langle f\rangle\right\|+\frac{\sqrt{T}}{2}\|f\|_{L^{2}(] 0, T[; H)}+\frac{T}{2}\left\|f^{\prime}\right\|_{L^{1}(] 0, T[; H)}
$$

and

$$
\left\|x^{\prime}\right\|_{L^{\infty}(j 0, T[; H)} \leq \frac{1}{\sqrt{T}}\|f\|_{L^{2}(] 0, T[; H)}+\left\|f^{\prime}\right\|_{L^{1}(] 0, T[; H)}
$$

and the solution is unique up to a constant in $A^{-1}(0)$.
Proof The condition is necessary (see Proposition 3.3). Let us show now that it is also sufficient. Consider the $T$-periodic solutions $\left(x_{\alpha}\right)_{\alpha>0}$ for

$$
\alpha x_{\alpha}(t)+x_{\alpha}^{\prime}(t)+A x_{\alpha}(t)=f(t), \quad t \in[0, T], \alpha>0
$$

First we prove that $\left(x_{\alpha}\right)_{\alpha>0}$ is uniformly bounded in $C^{1}([0, T] ; H)$. Let us multiply by $x_{\alpha}^{\prime}(t)$ and integrate on a period:

$$
\int_{0}^{T}\left\|x_{\alpha}^{\prime}(t)\right\|^{2} d t+\int_{0}^{T} \alpha\left(x_{\alpha}(t), x_{\alpha}^{\prime}(t)\right)+\left(A x_{\alpha}(t), x_{\alpha}^{\prime}(t)\right) d t=\int_{0}^{T}\left(f(t), x_{\alpha}^{\prime}(t)\right) d t
$$

Since $A$ is symmetric and $x_{\alpha}$ is $T$-periodic we have

$$
\begin{aligned}
& \int_{0}^{T} \alpha\left(x_{\alpha}(t), x_{\alpha}^{\prime}(t)\right)+\left(A x_{\alpha}(t), x_{\alpha}^{\prime}(t)\right) d t \\
& \quad= \int_{0}^{T} \frac{\alpha}{2} \frac{d}{d t}\left\|x_{\alpha}(t)\right\|^{2} d t+\int_{0}^{T} \frac{1}{2} \frac{d}{d t}\left(A x_{\alpha}(t), x_{\alpha}(t)\right) d t \\
& \quad=\left.\frac{1}{2}\left\{\alpha\left\|x_{\alpha}(t)\right\|^{2}+\left(A x_{\alpha}(t), x_{\alpha}(t)\right)\right\}\right|_{0} ^{T}=0
\end{aligned}
$$

Finally we get

$$
\left\|x_{\alpha}^{\prime}\right\|_{L^{2}(] 0, T[; H)}^{2} \leq\left(f, x_{\alpha}^{\prime}\right)_{L^{2}(] 0, T[; H)} \leq\|f\|_{L^{2}(] 0, T[; H)} \cdot\left\|x_{\alpha}^{\prime}\right\|_{L^{2}(] 0, T[; H)}
$$

and hence

$$
\left\|x_{\alpha}^{\prime}\right\|_{L^{2}(] 0, T[; H)} \leq\|f\|_{L^{2}(] 0, T[; H)}, \quad \alpha>0 .
$$

Therefore we can write

$$
\begin{equation*}
\min _{t \in[0, T]}\left\|x_{\alpha}^{\prime}(t)\right\| \leq \frac{1}{\sqrt{T}}\left\|x_{\alpha}^{\prime}\right\|_{L^{2}(] 0, T[; H)} \leq \frac{1}{\sqrt{T}}\|f\|_{L^{2}(] 0, T[; H)} \tag{43}
\end{equation*}
$$

As seen before, since $A$ is linear we can write

$$
\begin{aligned}
\frac{\alpha}{h}\left(x_{\alpha}(t+h)-x_{\alpha}(t)\right) & +\frac{1}{h}\left(x_{\alpha}^{\prime}(t+h)-x_{\alpha}^{\prime}(t)\right) \\
& +\frac{1}{h} A\left(x_{\alpha}(t+h)-x_{\alpha}(t)\right) \quad=\frac{1}{h}(f(t+h)-f(t))
\end{aligned}
$$

and by standard calculations for $s<t$ and $h>0$, we get

$$
\begin{aligned}
& \frac{1}{h}\left\|x_{\alpha}(t+h)-x_{\alpha}(t)\right\| \\
& \quad \leq e^{-\alpha(t-s)} \frac{1}{h}\left\|x_{\alpha}(s+h)-x_{\alpha}(s)\right\|+\int_{s}^{t} e^{-\alpha(t-\tau)} \frac{1}{h}\|f(\tau+h)-f(t)\| d \tau
\end{aligned}
$$

Passing to the limit for $h \rightarrow 0$ we deduce

$$
\begin{align*}
\left\|x_{\alpha}^{\prime}(t)\right\| & \leq e^{-\alpha(t-s)}\left\|x_{\alpha}^{\prime}(s)\right\|+\int_{s}^{t} e^{-\alpha(t-\tau)}\left\|f^{\prime}(\tau)\right\| d \tau \\
& \leq\left\|x_{\alpha}^{\prime}(s)\right\|+\int_{s}^{t}\left\|f^{\prime}(\tau)\right\| d \tau, \quad s \leq t, \alpha>0 \tag{44}
\end{align*}
$$

From (43) and (44) we conclude that the functions $\left(x_{\alpha}^{\prime}\right)_{\alpha>0}$ are uniformly bounded in $L^{\infty}(] 0, T[; H)$ :

$$
\left\|x_{\alpha}^{\prime}\right\|_{L^{\infty}(] 0, T[; H)} \leq \frac{1}{\sqrt{T}}\|f\|_{L^{2}(] 0, T[; H)}+\left\|f^{\prime}\right\|_{L^{1}(] 0, T[; H)}, \quad \alpha>0 .
$$

As shown before, since $A$ is linear and $x_{\alpha}$ is $T$-periodic we have also

$$
\begin{equation*}
\alpha\left\langle x_{\alpha}\right\rangle+A\left\langle x_{\alpha}\right\rangle=\langle f\rangle . \tag{45}
\end{equation*}
$$

By the hypothesis there is $x_{0} \in D(A)$ such that $\langle f\rangle=A x_{0}$ and hence

$$
\left\|\left\langle x_{\alpha}\right\rangle\right\|=\left\|(\alpha+A)^{-1}\langle f\rangle\right\|=\left\|(\alpha+A)^{-1} A x_{0}\right\| \leq\left\|x_{0}\right\|, \quad \alpha>0 .
$$

Now it is easy to check that $\left(x_{\alpha}\right)_{\alpha>0}$ is uniformly bounded in $L^{\infty}(] 0, T[; H)$ :

$$
\begin{aligned}
\left\|x_{\alpha}(t)-\left\langle x_{\alpha}\right\rangle\right\| & =\left\|\frac{1}{T} \int_{0}^{T}\left(x_{\alpha}(t)-x_{\alpha}(s)\right) d s\right\| \\
& =\left\|\frac{1}{T} \int_{0}^{T} \int_{s}^{t} x_{\alpha}^{\prime}(\tau) d \tau d s\right\| \\
& \leq \frac{\sqrt{T}}{2}\|f\|_{L^{2}(] 0, T[; H)}+\frac{T}{2}\left\|f^{\prime}\right\|_{L^{1}(] 0, T[; H)}
\end{aligned}
$$

and thus

$$
\begin{aligned}
\left\|x_{\alpha}\right\|_{L^{\infty}(] 0, T[; H)} & \leq\left\|\left\langle x_{\alpha}\right\rangle\right\|+\frac{\sqrt{T}}{2}\|f\|_{L^{2}(] 0, T[; H)}+\frac{T}{2}\left\|f^{\prime}\right\|_{L^{1}(] 0, T[; H)} \\
& \leq\left\|x_{0}\right\|+\frac{\sqrt{T}}{2}\|f\|_{L^{2}(] 0, T[; H)}+\frac{T}{2}\left\|f^{\prime}\right\|_{L^{1}(] 0, T[; H)}
\end{aligned}
$$

Now we can prove that $\left(x_{\alpha}\right)_{\alpha>0}$ is convergent in $C^{1}([0, T] ; H)$. Indeed, by taking the difference between the equations (39) written for $\alpha, \beta>0$, after multiplication by $x_{\alpha}^{\prime}(t)-x_{\beta}^{\prime}(t)$ and integration on $[0, T]$ we get

$$
\begin{aligned}
& \int_{0}^{T}\left\{\alpha\left(x_{\alpha}(t)-x_{\beta}(t), x_{\alpha}^{\prime}(t)-x_{\beta}^{\prime}(t)\right)\right. \\
& \left.+\left\|x_{\alpha}^{\prime}(t)-x_{\beta}^{\prime}(t)\right\|^{2}+\left(A\left(x_{\alpha}(t)-x_{\beta}(t)\right), x_{\alpha}^{\prime}(t)-x_{\beta}^{\prime}(t)\right)\right\} d t \\
& \quad=\quad-(\alpha-\beta) \int_{0}^{T}\left(x_{\beta}(t), x_{\alpha}^{\prime}(t)-x_{\beta}^{\prime}(t)\right) d t .
\end{aligned}
$$

Since $A$ is symmetric, $x_{\alpha}$ and $x_{\beta}$ are $T$-periodic and uniformly bounded in $L^{\infty}(] 0, T[; H)$ we deduce that

$$
\left\|x_{\alpha}^{\prime}-x_{\beta}^{\prime}\right\|_{L^{2}(] 0, T[; H)} \leq|\alpha-\beta| \cdot \sup _{\gamma>0}\left\|x_{\gamma}\right\|_{L^{2}(] 0, T[; H)},
$$

or
$\left\|x_{\alpha}^{\prime}-x_{\beta}^{\prime}\right\|_{L^{\infty}(] 0, T[; H)} \leq \frac{|\alpha-\beta|}{\sqrt{T}} \cdot \sup _{\gamma>0}\left\|x_{\gamma}\right\|_{L^{2}(] 0, T[; H)}+|\alpha-\beta| \cdot \sup _{\gamma>0}\left\|x_{\gamma}^{\prime}\right\|_{L^{1}(] 0, T[; H)}$,
and therefore $\left(x_{\alpha}^{\prime}\right)_{\alpha>0}$ converges in $C([0, T] ; H)$.
We already know that $\left(\left\langle x_{\alpha}\right\rangle\right)_{\alpha>0}=\left((\alpha+A)^{-1}\langle f\rangle\right)_{\alpha>0}$ is bounded in $H$ and by the Proposition 3.6 it follows that $\left(\left\langle x_{\alpha}\right\rangle\right)_{\alpha>0}$ is convergent to the element of minimal norm in $A^{-1}\langle f\rangle$. We have

$$
x_{\alpha}(t)=x_{\alpha}(0)+\int_{0}^{t} x_{\alpha}^{\prime}(s) d s, \quad t \in \mathbb{R}, \alpha>0
$$

By taking the average we deduce that $x_{\alpha}(0)=\left\langle x_{\alpha}\right\rangle-<\int_{0}^{t} x_{\alpha}^{\prime}(s) d s>$ and therefore, since $\left(x_{\alpha}^{\prime}\right)_{\alpha>0}$ is uniformly convergent, it follows that $\left(x_{\alpha}(0)\right)_{\alpha>0}$ is also convergent. Finally we conclude that $\left(x_{\alpha}\right)_{\alpha>0}$ is convergent in $C^{1}([0, T] ; H)$ to the periodic solution $x$ for (33) such that $\langle x\rangle$ is the element of minimal norm in $A^{-1}\langle f\rangle$.

Before analyzing the periodic solution for the heat equation, following an idea of [7], let us state the following proposition.

Proposition 3.9 Assume that $A: D(A) \subset H \rightarrow H$ is a linear maximal monotone and symmetric operator and $f \in C^{1}([0, T] ; H)$ is a T-periodic function. Then for every $x_{0} \in D(A)$ we have

$$
\begin{equation*}
\lim _{t \rightarrow \infty} \frac{1}{T}\left(x\left(t+T ; 0, x_{0}\right)-x\left(t ; 0, x_{0}\right)\right)=\langle f\rangle-\operatorname{Proj}_{\overline{R(A)}}\langle f\rangle \tag{46}
\end{equation*}
$$

where $x\left(\cdot ; 0, x_{0}\right)$ represents the solution of (33) with the initial data $x_{0}$ and $R(A)$ is the range of $A$.

Remark 3.10 $A$ being maximal monotone, $A^{-1}$ is also maximal monotone and therefore $\overline{D\left(A^{-1}\right)}=\overline{R(A)}$ is convex.

Proof of Proposition 3.9. Consider $x_{0} \in D(A)$ and denote by $x(\cdot)$ the corresponding solution. By integration on $[t, t+T]$ we get

$$
\begin{equation*}
\frac{1}{T}(x(t+T)-x(t))+A\left(\frac{1}{T} \int_{t}^{t+T} x(s) d s\right)=\langle f\rangle \tag{47}
\end{equation*}
$$

For each $\alpha>0$ consider $x_{\alpha} \in D(A)$ such that $\alpha x_{\alpha}+A x_{\alpha}=\langle f\rangle$. Denoting by $y(\cdot)$ the function $y(t)=\frac{1}{T} \int_{t}^{t+T} x(s) d s, \quad t \geq 0$, equation (47) writes

$$
y^{\prime}(t)+A y(t)=\alpha x_{\alpha}+A x_{\alpha}, \quad t \geq 0, \alpha>0 .
$$

Let us search for $y$ of the form $y_{1}+y_{2}$ where

$$
y_{1}^{\prime}(t)+A y_{1}(t)=\alpha x_{\alpha}, \quad t \geq 0
$$

with the initial condition $y_{1}(0)=0$ and

$$
\begin{equation*}
y_{2}^{\prime}(t)+A y_{2}(t)=A x_{\alpha}, \quad t \geq 0 \tag{48}
\end{equation*}
$$

with the initial condition $y_{2}(0)=y(0)=\frac{1}{T} \int_{0}^{T} x(t) d t$. We are interested on the asymptotic behaviour of $A y(t)=A y_{1}(t)+A y_{2}(t)$ for large $t$. We have

$$
\begin{aligned}
y_{1}(t) & =e^{-t A} y_{1}(0)+\int_{0}^{t} e^{-(t-s) A} \alpha x_{\alpha} d s \\
& =\int_{0}^{t} e^{-(t-s) A} \alpha x_{\alpha} d s
\end{aligned}
$$

and therefore,

$$
A y_{1}(t)=\int_{0}^{t} A e^{-(t-s) A} \alpha x_{\alpha} d s=\left.e^{-(t-s) A} \alpha x_{\alpha}\right|_{0} ^{t}=\left(1-e^{-t A}\right) \alpha x_{\alpha}
$$

By the other hand, after multiplication of (48) by $y_{2}^{\prime}(t)=\left(y_{2}(t)-x_{\alpha}\right)^{\prime}$ we get

$$
\left\|y_{2}^{\prime}(t)\right\|^{2}+\left(A\left(y_{2}(t)-x_{\alpha}\right),\left(y_{2}(t)-x_{\alpha}\right)^{\prime}\right)=0, \quad t \geq 0
$$

Since $A$ is symmetric, after integration on $[0, t]$ we obtain

$$
\int_{0}^{t}\left\|y_{2}^{\prime}(s)\right\|^{2} d s+\frac{1}{2}\left(A\left(y_{2}(t)-x_{\alpha}\right), y_{2}(t)-x_{\alpha}\right)=\frac{1}{2}\left(A\left(y_{2}(0)-x_{\alpha}\right), y_{2}(0)-x_{\alpha}\right)
$$

and therefore, by the monotony of $A$ it follows that

$$
\int_{0}^{\infty}\left\|y_{2}^{\prime}(t)\right\|^{2} d t \leq \frac{1}{2}\left(A\left(y_{2}(0)-x_{\alpha}\right), y_{2}(0)-x_{\alpha}\right)
$$

Thus $\lim _{t \rightarrow \infty} y_{2}^{\prime}(t)=0$ and by passing to the limit in (48) we deduce that $\lim _{t \rightarrow \infty} A y_{2}(t)=\lim _{t \rightarrow \infty}\left(A x_{\alpha}-y_{2}^{\prime}(t)\right)=A x_{\alpha}$. Finally we find that

$$
\begin{align*}
& \lim _{t \rightarrow \infty}\left\{\frac{1}{T}(x(t+T)-x(t))-e^{-t A} \alpha x_{\alpha}\right\} \\
& \quad= \lim _{t \rightarrow \infty}\left\{y^{\prime}(t)-e^{-t A} \alpha x_{\alpha}\right\} \\
& \quad=\lim _{t \rightarrow \infty}\left\{\langle f\rangle-A y(t)-e^{-t A} \alpha x_{\alpha}\right\} \\
& \quad=\lim _{t \rightarrow \infty}\left\{\langle f\rangle-A y_{1}(t)-A y_{2}(t)-e^{-t A} \alpha x_{\alpha}\right\} \\
& \quad=\langle f\rangle-\alpha x_{\alpha}-A x_{\alpha}=0, \quad \alpha>0 . \tag{49}
\end{align*}
$$

Now let us put $y_{\alpha}=A x_{\alpha}$ and observe that $y_{\alpha}+\alpha A^{-1} y_{\alpha}=A x_{\alpha}+\alpha x_{\alpha}=$ $\langle f\rangle, \quad \alpha>0$. Therefore,

$$
\begin{aligned}
\lim _{\alpha \searrow 0} y_{\alpha} & =\lim _{\alpha \searrow 0}\left(1+\alpha A^{-1}\right)^{-1}\langle f\rangle \\
& =\lim _{\alpha \searrow 0} J_{\alpha}^{A^{-1}}\langle f\rangle \\
& =\operatorname{Proj}_{\overline{D\left(A^{-1}\right)}}\langle f\rangle \\
& =\operatorname{Proj}_{\overline{R(A)}}\langle f\rangle,
\end{aligned}
$$

and it follows that

$$
\lim _{\alpha \searrow 0} \alpha x_{\alpha}=\lim _{\alpha \searrow 0}\left(\langle f\rangle-A x_{\alpha}\right)=\lim _{\alpha \searrow 0}\left(\langle f\rangle-y_{\alpha}\right)=\langle f\rangle-\operatorname{Proj}_{\overline{R(A)}}\langle f\rangle .
$$

Since $\operatorname{Graph}(A)$ is closed and $\left[\alpha x_{\alpha}, \alpha y_{\alpha}\right]=\left[\alpha x_{\alpha}, A\left(\alpha x_{\alpha}\right)\right] \in A, \alpha>0$, by passing to the limit for $\alpha \searrow 0$ we deduce that $\langle f\rangle-\operatorname{Proj} \frac{{ }_{R(A)}}{}\langle f\rangle \in D(A)$ and $A\left(\langle f\rangle-\operatorname{Proj}_{\overline{R(A)}}\langle f\rangle\right)=0$. It is easy to see that we can pass to the limit for $\alpha \searrow 0$ in (49). Indeed, for $\varepsilon>0$ let us consider $\alpha_{\varepsilon}>0$ such that $\| \lim _{\alpha \searrow 0} \alpha x_{\alpha}-$ $\alpha_{\varepsilon} x_{\alpha_{\varepsilon}} \|<\frac{\varepsilon}{2}$. We have

$$
\begin{aligned}
& \left\|\frac{1}{T}(x(t+T)-x(t))-e^{-t A} \lim _{\alpha \searrow 0} \alpha x_{\alpha}\right\| \\
& \quad \leq\left\|\frac{1}{T}(x(t+T)-x(t))-e^{-t A} \alpha_{\varepsilon} x_{\alpha_{\varepsilon}}\right\|+\left\|e^{-t A} \alpha_{\varepsilon} x_{\alpha_{\varepsilon}}-e^{-t A} \lim _{\alpha \searrow 0} \alpha x_{\alpha}\right\| \\
& \quad \leq\left\|\frac{1}{T}(x(t+T)-x(t))-e^{-t A} \alpha_{\varepsilon} x_{\alpha_{\varepsilon}}\right\|+\left\|\alpha_{\varepsilon} x_{\alpha_{\varepsilon}}-\lim _{\alpha \searrow 0} \alpha x_{\alpha}\right\| \\
& \quad \leq \frac{\varepsilon}{2}+\frac{\varepsilon}{2}=\varepsilon, \quad t \geq t\left(\alpha_{\varepsilon}, \frac{\varepsilon}{2}\right)=t(\varepsilon),
\end{aligned}
$$

and thus

$$
\lim _{t \rightarrow \infty}\left\{\frac{1}{T}(x(t+T)-x(t))-e^{-t A}\left(\langle f\rangle-\operatorname{Proj}_{\overline{R(A)}}\langle f\rangle\right)\right\}=0
$$

But $e^{-t A}\left(\langle f\rangle-\operatorname{Proj}_{\overline{R(A)}}\langle f\rangle\right)$ does not depend on $t \geq 0$ :

$$
\begin{aligned}
\frac{d}{d t} e^{-t A}\left(\langle f\rangle-\operatorname{Proj}_{\overline{R(A)}}\langle f\rangle\right) & =-A e^{-t A}\left(\langle f\rangle-\operatorname{Proj}_{\overline{R(A)}}\langle f\rangle\right) \\
& =-e^{-t A} A\left(\langle f\rangle-\operatorname{Proj}_{\overline{R(A)}}\langle f\rangle\right)=0
\end{aligned}
$$

and thus the previous formula reads

$$
\lim _{t \rightarrow \infty} \frac{1}{T}(x(t+T)-x(t))=\langle f\rangle-\operatorname{Proj}_{\overline{R(A)}}\langle f\rangle .
$$

Remark 3.11 Under the same hypothesis as above we can easily check that

$$
\inf _{x_{0} \in D(A)} \frac{\left\|x\left(T ; 0, x_{0}\right)-x_{0}\right\|}{T}=\left\|\langle f\rangle-\operatorname{Proj}_{\overline{R(A)}}\langle f\rangle\right\|=\operatorname{dist}(\langle f\rangle, \overline{R(A)}) .
$$

### 3.3 Periodic solutions for the heat equation

Let $\Omega \subset \mathbb{R}^{d}, d \geq 1$, be an open bounded set with $\partial \Omega \in C^{2}$. Consider the heat equation

$$
\begin{equation*}
\frac{\partial u}{\partial t}(t, x)-\Delta u(t, x)=f(t, x), \quad(t, x) \in \mathbb{R} \times \Omega \tag{50}
\end{equation*}
$$

with the Dirichlet boundary condition

$$
\begin{equation*}
u(t, x)=g(t, x), \quad(t, x) \in \mathbb{R} \times \partial \Omega, \tag{51}
\end{equation*}
$$

or the Neumann boundary condition

$$
\begin{equation*}
\frac{\partial u}{\partial n}(t, x)=g(t, x), \quad(t, x) \in \mathbb{R} \times \partial \Omega \tag{52}
\end{equation*}
$$

where we denote by $n(x)$ the outward normal in $x \in \partial \Omega$.
Theorem 3.12 Assume that $f \in C^{1}\left(\mathbb{R} ; L^{2}(\Omega)\right)$ is $T$-periodic and $g(t, x)=$ $\frac{\partial u_{0}}{\partial n}(t, x),(t, x) \in \mathbb{R} \times \partial \Omega$ where $u_{0} \in C^{1}\left(\mathbb{R} ; H^{2}(\Omega)\right) \cap C^{2}\left(\mathbb{R} ; L^{2}(\Omega)\right)$ is T-periodic. Then the heat problem (50), (52) has T-periodic solutions $u \in C\left(\mathbb{R} ; H^{2}(\Omega)\right) \cap$ $C^{1}\left(\mathbb{R} ; L^{2}(\Omega)\right)$ if and only if

$$
\int_{\partial \Omega} \int_{0}^{T} g(t, x) d t d \sigma+\int_{\Omega} \int_{0}^{T} f(t, x) d t d x=0
$$

In this case the periodic solutions satisfies the estimates

$$
\begin{align*}
\left\|u^{\prime}-u_{0}^{\prime}\right\|_{L^{\infty}\left([0, T] ; L^{2}(\Omega)\right)} & \leq \frac{1}{\sqrt{T}}\left\|f-u_{0}^{\prime}+\Delta u_{0}\right\|_{L^{2}(] 0, T\left[; L^{2}(\Omega)\right)} \\
& +\left\|f^{\prime}-u_{0}^{\prime \prime}+\Delta u_{0}^{\prime}\right\|_{L^{1}(] 0, T\left[; L^{2}(\Omega)\right)}, \tag{53}
\end{align*}
$$

and the solution is unique up to a constant.

Proof Let us search for solutions $u=u_{0}+v$ where

$$
\begin{equation*}
\frac{\partial v}{\partial t}(t, x)-\Delta v(t, x)=f(t, x)-\frac{\partial u_{0}}{\partial t}(t, x)+\Delta u_{0}(t, x), \quad(t, x) \in \mathbb{R} \times \Omega, \tag{54}
\end{equation*}
$$

and

$$
\begin{equation*}
\frac{\partial v}{\partial n}(t, x)=g(t, x)-\frac{\partial u_{0}}{\partial n}(t, x)=0, \quad(t, x) \in \mathbb{R} \times \partial \Omega . \tag{55}
\end{equation*}
$$

Consider the operator $A_{N}: D\left(A_{N}\right) \subset L^{2}(\Omega) \rightarrow L^{2}(\Omega)$ given as

$$
A_{N} v=-\Delta v
$$

with domain

$$
D\left(A_{N}\right)=\left\{v \in H^{2}(\Omega): \frac{\partial v}{\partial n}(x)=0, \forall x \in \partial \Omega\right\}
$$

The operator $A_{N}$ is linear monotone:

$$
\begin{align*}
\left(A_{N} v, v\right) & =-\int_{\Omega} \Delta v(x) v(x) d x \\
& =-\int_{\partial \Omega} \frac{\partial v}{\partial n}(x) v(x) d \sigma+\int_{\Omega}\|\nabla v(x)\|^{2} d x \\
& =\int_{\Omega}\|\nabla v(x)\|^{2} d x \geq 0, \quad \forall v \in D\left(A_{N}\right) \tag{56}
\end{align*}
$$

Since the equation $\lambda v-\Delta v=f$ has unique solution in $D\left(A_{N}\right)$ for every $f \in$ $L^{2}(\Omega), \lambda>0$ it follows that $A_{N}$ is maximal (see [6]). Moreover, it is symmetric

$$
\left(A_{N} v_{1}, v_{2}\right)=\int_{\Omega} \nabla v_{1}(x) \cdot \nabla v_{2}(x) d x=\left(v_{1}, A_{N} v_{2}\right), \quad \forall v_{1}, v_{2} \in D\left(A_{N}\right)
$$

Note that by the hypothesis the second member in (54) $f-u_{0}^{\prime}+\Delta u_{0}$ belongs to $C^{1}\left(\mathbb{R} ; L^{2}(\Omega)\right)$. Therefore the Theorem 3.8 applies and hence the problem (54), (55) has periodic solutions if and only if there is $w \in D\left(A_{N}\right)$ such that

$$
-\Delta w=\frac{1}{T} \int_{0}^{T}\left\{f(t)-\frac{d u_{0}}{d t}(t)+\Delta u_{0}(t)\right\} d t
$$

Since $u_{0}$ is $T$-periodic we have $\int_{0}^{T} \frac{d u_{0}}{d t}(t) d t=0$ and thus $w+\frac{1}{T} \int_{0}^{T} u_{0}(t) d t$ is solution for the elliptic problem

$$
-\Delta\left(w+\frac{1}{T} \int_{0}^{T} u_{0}(t) d t\right)=\frac{1}{T} \int_{0}^{T} f(t) d t=F
$$

with the boundary condition

$$
\begin{aligned}
\frac{\partial}{\partial n}\left(w+\frac{1}{T} \int_{0}^{T} u_{0}(t) d t\right) & =\frac{\partial w}{\partial n}+\frac{1}{T} \int_{0}^{T} \frac{\partial u_{0}}{\partial n}(t) d t \\
& =\frac{1}{T} \int_{0}^{T} g(t) d t=G
\end{aligned}
$$

As known from the general theory of partial differential equations (see [6]) this problem has solution if and only if $\int_{\partial \Omega} G(x) d \sigma+\int_{\Omega} F(x) d x=0$ or

$$
\int_{\partial \Omega} \int_{0}^{T} g(t, x) d t d \sigma+\int_{\Omega} \int_{0}^{T} f(t, x) d t d x=0
$$

The estimate (53) follows from Theorem 3.8.
For the heat equation with Dirichlet boundary condition we have the following existence result.

Theorem 3.13 Assume that $f \in C^{1}\left(\mathbb{R} ; L^{2}(\Omega)\right)$ is T-periodic and $g(t, x)=$ $u_{0}(t, x),(t, x) \in \mathbb{R} \times \partial \Omega$ where $u_{0} \in C^{1}\left(\mathbb{R} ; H^{2}(\Omega)\right) \cap C^{2}\left(\mathbb{R} ; L^{2}(\Omega)\right)$ is $T$-periodic. Then the heat problem (50), (51) has an unique T-periodic solution $u$ in $C\left(\mathbb{R} ; H^{2}(\Omega)\right) \cap C^{1}\left(\mathbb{R} ; L^{2}(\Omega)\right)$ and there is a constant $C(\Omega)$ such that

$$
\begin{align*}
\left\|u-u_{0}\right\|_{L^{\infty}\left([0, T] ; L^{2}(\Omega)\right)} \leq & C(\Omega)\left\|f+\Delta u_{0}\right\|_{L^{\infty}\left([0, T] ; L^{2}(\Omega)\right)} \\
& +\frac{\sqrt{T}}{2}\left\|f-u_{0}^{\prime}+\Delta u_{0}\right\|_{L^{2}(] 0, T\left[; L^{2}(\Omega)\right)} \\
& +\frac{T}{2}\left\|f^{\prime}-u_{0}^{\prime \prime}+\Delta u_{0}^{\prime}\right\|_{L^{1}(] 0, T\left[; L^{2}(\Omega)\right)} \tag{57}
\end{align*}
$$

and

$$
\begin{align*}
\left\|u^{\prime}-u_{0}^{\prime}\right\|_{L^{\infty}\left([0, T] ; L^{2}(\Omega)\right)} \leq & \frac{1}{\sqrt{T}}\left\|f-u_{0}^{\prime}+\Delta u_{0}\right\|_{L^{2}(] 0, T\left[; L^{2}(\Omega)\right)} \\
& +\left\|f^{\prime}-u_{0}^{\prime \prime}+\Delta u_{0}^{\prime}\right\|_{L^{1}(] 0, T\left[; L^{2}(\Omega)\right)} . \tag{58}
\end{align*}
$$

Proof This time we consider the operator $A_{D}: D\left(A_{D}\right) \subset L^{2}(\Omega) \rightarrow L^{2}(\Omega)$ given as

$$
A_{D} v=-\Delta v
$$

with domain

$$
D\left(A_{D}\right)=\left\{v \in H^{2}(\Omega): v(x)=0, \forall x \in \partial \Omega\right\},
$$

As before $A_{D}$ is linear, monotone and symmetric and thus our problem reduces to the existence for an elliptic equation:

$$
-\Delta w=\frac{1}{T} \int_{0}^{T}\left\{f(t)+\Delta u_{0}(t)\right\} d t
$$

with homogenous Dirichlet boundary condition $w=0$ on $\partial \Omega$. Since the previous problem has a unique solution verifying

$$
\begin{align*}
\|w\|_{L^{2}(\Omega)} & \leq C(\Omega)\left\|\frac{1}{T} \int_{0}^{T}\left\{f(t)+\Delta u_{0}(t)\right\} d t\right\|_{L^{2}(\Omega)} \\
& \leq C(\Omega)\left\|f+\Delta u_{0}\right\|_{L^{\infty}\left([0, T] ; L^{2}(\Omega)\right)}, \tag{59}
\end{align*}
$$

we prove the existence for (50), (51). Here we denote by $C(\Omega)$ the Poincaré's constant,

$$
\left(\int_{\Omega}|w(x)|^{2} d x\right)^{1 / 2} \leq C(\Omega)\left(\int_{\Omega}\|\nabla w(x)\|^{2} d x\right)^{1 / 2}, \quad \forall w \in H_{0}^{1}(\Omega) .
$$

Moreover in this case the operator $A_{D}$ is strictly monotone. Indeed, by using the Poincaré's inequality, for each $v \in D\left(A_{D}\right)$, we have have

$$
\left(\int_{\Omega}|v(x)|^{2} d x\right)^{1 / 2} \leq C(\Omega)\left(\int_{\Omega}\|\nabla v(x)\|^{2} d x\right)^{1 / 2}=C(\Omega)\left(A_{D} v, v\right)^{1 / 2}
$$

Hence if $\left(A_{D} v, v\right)=0$ we deduce that $v=0$. Therefore, by Proposition 3.2 we deduce the uniqueness of the periodic solution for (50), (51). The estimates of the solution follow immediately from (59) and Theorem 3.8.

### 3.4 Non-linear case

Throughout this section we will consider evolution equations associated to subdifferential operators. Let $\varphi: H \rightarrow]-\infty,+\infty]$ be a lower-semicontinuous proper convex function on a real Hilbert space $H$. Denote by $\partial \varphi \subset H \times H$ the subdifferential of $\varphi$,

$$
\begin{equation*}
\partial \varphi(x)=\{y \in H ; \varphi(x)-\varphi(u) \leq(y, x-u), \forall u \in H\} \tag{60}
\end{equation*}
$$

and denote by $D(\varphi)$ the effective domain of $\varphi$ :

$$
D(\varphi)=\{x \in H ; \varphi(x)<+\infty\} .
$$

Under the previous assumptions on $\varphi$ we recall that $A=\partial \varphi$ is maximal monotone in $H \times H$ and $\overline{D(A)}=\overline{D(\varphi)}$. Consider the equation

$$
\begin{equation*}
x^{\prime}(t)+\partial \varphi x(t) \ni f(t), \quad 0<t<T \tag{61}
\end{equation*}
$$

We say that $x$ is solution for (61) if $x \in C([0, T] ; H), x$ is absolutely continuous on every compact of $] 0, T[$ (and therefore a.e. differentiable on $] 0, T[$ ) and satisfies $x(t) \in D(\partial \varphi)$ a.e. on $] 0, T\left[\right.$ and $x^{\prime}(t)+\partial \varphi x(t) \ni f(t)$ a.e. on $] 0, T[$. We have the following main result [1]

Theorem 3.14 Let $f$ be given in $L^{2}(] 0, T[; H)$ and $x_{0} \in \overline{D(\partial \varphi)}$. Then the Cauchy problem (61) with the initial condition $x(0)=x_{0}$ has a unique solution $x \in C([0, T] ; H)$ which satisfies:
$x \in W^{1,2}(] \delta, T[; H) \quad \forall 0<\delta<T, \quad \sqrt{t} \cdot x^{\prime} \in L^{2}(] 0, T[; H), \quad \varphi \circ x \in L^{1}(0, T)$. Moreover, if $x_{0} \in D(\varphi)$ then

$$
x^{\prime} \in L^{2}(] 0, T[; H), \quad \varphi \circ x \in L^{\infty}(0, T)
$$

We are interested in finding sufficient conditions on $A=\partial \varphi$ and $f$ such that equation (61) has unique $T$-periodic solution, i.e. $x(0)=x(T)$. Obviously, if such a solution exists, by periodicity we deduce that it is absolutely continuous on $[0, T]$ and belongs to $W^{1,2}(] 0, T[; H)$. It is well known that if $\varphi$ is strictly convex then $\partial \varphi$ is strictly monotone and therefore the uniqueness holds

Proposition 3.15 Assume that $\varphi: H \rightarrow]-\infty,+\infty$ ] is a lower-semicontinuous proper, strictly convex function. Then equation (61) has at most one periodic solution.

Proof By using Proposition 3.2 it is sufficient to prove that $\partial \varphi$ is strictly monotone. Suppose that there are $u_{1}, u_{2} \in D(\partial \varphi), u_{1} \neq u_{2}$ such that

$$
\left(\partial \varphi\left(u_{1}\right)-\partial \varphi\left(u_{2}\right), u_{1}-u_{2}\right)=0
$$

We have

$$
\begin{aligned}
\varphi\left(u_{2}\right)-\varphi\left(u_{1}\right) & \geq\left(\partial \varphi\left(u_{1}\right), u_{2}-u_{1}\right) \\
& =-\left(\partial \varphi\left(u_{2}\right), u_{1}-u_{2}\right) \\
& \geq \varphi\left(u_{2}\right)-\varphi\left(u_{1}\right)
\end{aligned}
$$

and hence

$$
\varphi\left(u_{2}\right)-\varphi\left(u_{1}\right)=\left(\partial \varphi\left(u_{1}\right), u_{2}-u_{1}\right)
$$

We can also write for $\lambda \in] 0,1[$

$$
\begin{aligned}
\varphi\left((1-\lambda) u_{1}+\lambda u_{2}\right) & =\varphi\left(u_{1}+\lambda\left(u_{2}-u_{1}\right)\right) \\
& \geq \varphi\left(u_{1}\right)+\left(\partial \varphi\left(u_{1}\right), \lambda\left(u_{2}-u_{1}\right)\right) \\
& =\varphi\left(u_{1}\right)+\lambda\left(\partial \varphi\left(u_{1}\right), u_{2}-u_{1}\right) \\
& =\varphi\left(u_{1}\right)+\lambda\left(\varphi\left(u_{2}\right)-\varphi\left(u_{1}\right)\right) \\
& =(1-\lambda) \varphi\left(u_{1}\right)+\lambda \varphi\left(u_{2}\right) .
\end{aligned}
$$

Since $\varphi$ is strictly convex we have also

$$
\varphi\left((1-\lambda) u_{1}+\lambda u_{2}\right)<(1-\lambda) \varphi\left(u_{1}\right)+\lambda \varphi\left(u_{2}\right),
$$

which is in contradiction with the previous inequality. Thus $u_{1}=u_{2}$ and hence $\partial \varphi$ is strictly monotone. We state now the result concerning the existence of periodic solutions.

Theorem 3.16 Suppose that $\varphi: H \rightarrow]-\infty,+\infty]$ is a lower-semicontinuous proper convex function and $f \in L^{2}(] 0, T[; H)$ such that

$$
\begin{equation*}
\lim _{\|x\| \rightarrow \infty}\{\varphi(x)-(x,\langle f\rangle)\}=+\infty \tag{62}
\end{equation*}
$$

and every level subset $\left\{x \in H ; \varphi(x)+\|x\|^{2} \leq M\right\}$ is compact. Then equation (61) has $T$-periodic solutions $x \in C([0, T] ; H) \cap W^{1,2}(] 0, T[; H)$ which satisfy

$$
\left\|x^{\prime}\right\|_{L^{2}(] 0, T[; H)} \leq\|f\|_{L^{2}(] 0, T[; H)}, \quad x(t) \in D(\varphi) \forall t \in[0, T], \quad \varphi \circ x \in L^{\infty}(0, T)
$$

Before showing this result, notice that the condition (62) implies that the lower-semicontinuous proper convex function $\psi: H \rightarrow]-\infty,+\infty$ ] given by $\psi(x)=\varphi(x)-(x,\langle f\rangle)$ has a minimum point $x_{0} \in H$ and therefore $\langle f\rangle \in$ Range $(\partial \varphi)$ since $0=\partial \psi\left(x_{0}\right)=\partial \varphi\left(x_{0}\right)-\langle f\rangle$.

Proof As previous for every $\alpha>0$ we consider the unique periodic solution $x_{\alpha}$ for

$$
\begin{equation*}
\alpha x_{\alpha}(t)+x_{\alpha}^{\prime}(t)+\partial \varphi x_{\alpha}(t)=f(t), \quad 0<t<T . \tag{63}
\end{equation*}
$$

(In order to prove the existence and uniqueness of the periodic solution for (63) consider the application $S_{\alpha}: \overline{D(\partial \varphi)} \rightarrow \overline{D(\partial \varphi)}$ defined by $S_{\alpha}\left(x_{0}\right)=x\left(T ; 0, x_{0}\right)$,
where $x\left(\cdot ; 0, x_{0}\right)$ denote the unique solution of (63) with the initial condition $x_{0}$ and apply the Banach's fixed point theorem. By the previous theorem it follows that the periodic solution $x_{\alpha}$ is absolutely continuous on $[0, T]$ and belongs to $\left.C([0, T] ; H) \cap W^{1,2}(] 0, T[; H)\right)$. First of all we will show that $\left(x_{\alpha}^{\prime}\right)_{\alpha>0}$ is uniformly bounded in $L^{2}(] 0, T[; H)$. Indeed, after multiplication by $x_{\alpha}^{\prime}(t)$ we obtain

$$
\int_{0}^{T}\left\|x_{\alpha}^{\prime}(t)\right\|^{2} d t+\int_{0}^{T}\left\{\alpha\left(x_{\alpha}(t), x_{\alpha}^{\prime}(t)\right)+\left(\partial \varphi x_{\alpha}(t), x_{\alpha}^{\prime}(t)\right)\right\} d t=\int_{0}^{T}\left(f(t), x_{\alpha}^{\prime}(t)\right) d t .
$$

Since $x_{\alpha}$ is $T$-periodic we deduce that

$$
\begin{align*}
& \int_{0}^{T}\left\{\alpha\left(x_{\alpha}(t), x_{\alpha}^{\prime}(t)\right)+\left(\partial \varphi x_{\alpha}(t), x_{\alpha}^{\prime}(t)\right)\right\} d t \\
&=\int_{0}^{T} \frac{d}{d t}\left\{\frac{\alpha}{2}\left\|x_{\alpha}(t)\right\|^{2}+\varphi\left(x_{\alpha}(t)\right)\right\} d t \\
&=\frac{\alpha}{2}\left\|x_{\alpha}(t)\right\|^{2}+\left.\varphi\left(x_{\alpha}(t)\right)\right|_{0} ^{T}=0 . \tag{64}
\end{align*}
$$

Therefore, $\left\|x_{\alpha}^{\prime}\right\|_{L^{2}(] 0, T[; H)}^{2} \leq\left(f, x_{\alpha}^{\prime}\right)_{L^{2}(] 0, T[; H)}$ and thus

$$
\left\|x_{\alpha}^{\prime}\right\|_{L^{2}(\jmath 0, T[; H)} \leq\|f\|_{L^{2}(] 0, T\lceil; H)}, \quad \alpha>0 .
$$

Before estimate $\left(x_{\alpha}\right)_{\alpha>0}$, let us check that $\left(\alpha x_{\alpha}\right)_{\alpha>0}$ is bounded. By taking $x_{0} \in D(\partial \varphi)$, after standard calculation we find that

$$
\begin{equation*}
\left\|x_{\alpha}(t)-x_{0}\right\| \leq e^{-\alpha t}\left\|x_{\alpha}(0)-x_{0}\right\|+\int_{0}^{t} e^{-\alpha(t-s)}\left\|f(s)-\alpha x_{0}-\partial \varphi\left(x_{0}\right)\right\| d s \tag{65}
\end{equation*}
$$

Since $x_{\alpha}$ is $T$-periodic we can write

$$
\begin{aligned}
\left\|x_{\alpha}(t)-x_{0}\right\|= & \lim _{n \rightarrow \infty}\left\|x_{\alpha}(n T+t)-x_{0}\right\| \\
\leq & \lim _{n \rightarrow \infty}\left\{e^{-\alpha(n T+t)}\left\|x_{\alpha}(0)-x_{0}\right\|\right. \\
& \left.+\int_{0}^{n T+t} e^{-\alpha(n T+t-s)}\left\|f(s)-\alpha x_{0}-\partial \varphi\left(x_{0}\right)\right\| d s\right\} \\
\leq & \frac{1}{\alpha}\left\|\alpha x_{0}+\partial \varphi\left(x_{0}\right)\right\|+\lim _{n \rightarrow \infty} \int_{0}^{n T+t} e^{-\alpha(n T+t-s)}\|f(s)\| d s \\
\leq & \frac{1}{\alpha}\left\|\alpha x_{0}+\partial \varphi\left(x_{0}\right)\right\| \\
& +\lim _{n \rightarrow \infty}\left\{\left[1+e^{-\alpha t}\left(e^{-\alpha(n-1) T}+\cdots+e^{-\alpha T}+1\right)\right] \cdot\|f\|_{L^{1}}\right\} \\
= & \frac{1}{\alpha}\left\|\alpha x_{0}+\partial \varphi\left(x_{0}\right)\right\|+\left(1+\frac{e^{-\alpha t}}{1-e^{-\alpha T}}\right) \cdot\|f\|_{L^{1}(] 0, T\lceil; H)} \\
\leq & C_{1}\left(x_{0}, T,\|f\|_{L^{2}(] 0, T[; H)}\right)\left(1+\frac{1}{\alpha}\right), \quad 0 \leq t \leq T, \quad \alpha>0 .
\end{aligned}
$$

It follows that $\alpha\left\|x_{\alpha}(t)\right\| \leq C_{2}\left(x_{0}, T,\|f\|_{L^{2}(\mathrm{~J} 0, T[; H)}\right), 0 \leq t \leq T, 0<\alpha<1$. Now we can estimate $x_{\alpha}, \alpha>0$. After multiplication by $x_{\alpha}(t)$ and integration on $[0, T]$ we obtain

$$
\begin{equation*}
\int_{0}^{T} \alpha\left\|x_{\alpha}(t)\right\|^{2} d t+\int_{0}^{T}\left(\partial \varphi\left(x_{\alpha}(t)\right), x_{\alpha}(t)\right) d t=\int_{0}^{T}\left(f(t), x_{\alpha}(t)\right) d t \tag{66}
\end{equation*}
$$

We have

$$
\varphi\left(x_{0}\right) \geq \varphi\left(x_{\alpha}(t)\right)+\left(\partial \varphi\left(x_{\alpha}(t)\right), x_{0}-x_{\alpha}(t)\right), \quad t \in[0, T], \alpha>0
$$

Thus we deduce that for $\alpha>0$,

$$
\int_{0}^{T}\left(\partial \varphi\left(x_{\alpha}(t)\right), x_{\alpha}(t)\right) d t \geq \int_{0}^{T} \varphi\left(x_{\alpha}(t)\right) d t+\int_{0}^{T}\left\{\left(\partial \varphi\left(x_{\alpha}(t)\right), x_{0}\right)-\varphi\left(x_{0}\right)\right\} d t
$$

On the other hand for $0<\alpha<1$,

$$
\begin{aligned}
\int_{0}^{T}\left(\partial \varphi\left(x_{\alpha}(t)\right), x_{0}\right) d t & =\int_{0}^{T}\left(f(t)-\alpha x_{\alpha}(t)-x_{\alpha}^{\prime}(t), x_{0}\right) d t \\
& =\left(\int_{0}^{T} f(t) d t, x_{0}\right)-\int_{0}^{T}\left(\alpha x_{\alpha}(t), x_{0}\right) d t \\
& \geq-C_{3}\left(x_{0}, T,\|f\|_{L^{2}(] 0, T\lceil; H)}\right)
\end{aligned}
$$

Therefore,

$$
\begin{equation*}
\int_{0}^{T}\left(\partial \varphi\left(x_{\alpha}(t)\right), x_{\alpha}(t)\right) d t \geq \int_{0}^{T} \varphi\left(x_{\alpha}(t)\right) d t-C_{4}\left(x_{0}, T,\|f\|_{L^{2}(] 0, T[; H)}\right) \tag{67}
\end{equation*}
$$

Combining (66) and (67) we deduce that

$$
\begin{align*}
\int_{0}^{T} \varphi\left(x_{\alpha}(t)\right) d t & \leq C_{4}+\int_{0}^{T}\left(\partial \varphi\left(x_{\alpha}(t)\right), x_{\alpha}(t)\right) d t \\
& =C_{4}+\int_{0}^{T}\left(f(t), x_{\alpha}(t)\right) d t-\int_{0}^{T} \alpha\left\|x_{\alpha}(t)\right\|^{2} d t \\
& \leq C_{4}+\int_{0}^{T}\left(f(t), x_{\alpha}(t)\right) d t, \quad 0<\alpha<1 \tag{68}
\end{align*}
$$

On the other hand we have

$$
\begin{aligned}
\int_{0}^{T} & \left(f(t), x_{\alpha}(t)\right) d t \\
& =\int_{0}^{T}\left(f(t)-\langle f\rangle, x_{\alpha}(t)\right) d t+\left(\int_{0}^{T} x_{\alpha}(t) d t,\langle f\rangle\right) \\
& =\int_{0}^{T}\left(f(t)-\langle f\rangle, x_{\alpha}(0)+\int_{0}^{t} x_{\alpha}^{\prime}(s) d s\right) d t+T\left(\left\langle x_{\alpha}\right\rangle,\langle f\rangle\right) \\
& =\int_{0}^{T}\left(f(t)-\langle f\rangle, \int_{0}^{t} x_{\alpha}^{\prime}(s) d s\right) d t+T\left(\left\langle x_{\alpha}\right\rangle,\langle f\rangle\right) \\
& \leq \int_{0}^{T}\|f(t)-\langle f\rangle\| \cdot\left(\int_{0}^{t}\left\|x_{\alpha}^{\prime}(s)\right\|^{2} d s\right)^{1 / 2} \cdot t^{1 / 2} d t+T\left(\left\langle x_{\alpha}\right\rangle,\langle f\rangle\right) \\
& \leq\|f-\langle f\rangle\|_{L^{2}(] 0, T[; H)} \cdot\|f\|_{L^{2}(] 0, T[; H)} \cdot \frac{T}{\sqrt{2}}+T\left(\left\langle x_{\alpha}\right\rangle,\langle f\rangle\right)
\end{aligned}
$$

Finally we deduce that

$$
\begin{equation*}
\int_{0}^{T}\left\{\varphi\left(x_{\alpha}(t)\right)-\left(x_{\alpha}(t),\langle f\rangle\right)\right\} d t \leq C_{5}\left(x_{0}, T,\|f\|_{L^{2}(] 0, T[; H)}\right), \quad 0<\alpha<1, \tag{69}
\end{equation*}
$$

and thus there is $t_{\alpha} \in[0, T]$ such that

$$
\begin{equation*}
\varphi\left(x_{\alpha}(t)\right)-\left(x_{\alpha}(t),\langle f\rangle\right) \leq \frac{C_{5}}{T}, \quad 0<\alpha<1 \tag{70}
\end{equation*}
$$

From Hypothesis (62) we get that $\left(x_{\alpha}\left(t_{\alpha}\right)\right)_{0<\alpha<1}$ is bounded and therefore from (65), for $t \in\left[t_{\alpha}, t_{\alpha}+T\right]$,

$$
\left\|x_{\alpha}(t)-x_{0}\right\| \leq e^{-\alpha\left(t-t_{\alpha}\right)}\left\|x_{\alpha}\left(t_{\alpha}\right)-x_{0}\right\|+\int_{t_{\alpha}}^{t} e^{-\alpha(t-s)}\left\|f(s)-\alpha x_{0}-\partial \varphi\left(x_{0}\right)\right\| d s
$$

we deduce that $\left(x_{\alpha}\right)_{0<\alpha<1}$ is bounded in $L^{\infty}(] 0, T[; H)$ and that there is $x \in$ $L^{\infty}(] 0, T[; H)$ such that $x_{\alpha}(t) \rightharpoonup x(t)$ when $\alpha$ goes to 0 for $t \in[0, T]$. Moreover, from (70) it follows that $\left(\varphi\left(x_{\alpha}\left(t_{\alpha}\right)\right)\right)_{0<\alpha<1}$ is bounded from above and we deduce that

$$
\begin{aligned}
\varphi\left(x_{\alpha}(t)\right) & =\varphi\left(x_{\alpha}\left(t_{\alpha}\right)\right)+\int_{t_{\alpha}}^{t}\left(\partial \varphi\left(x_{\alpha}(s)\right), x_{\alpha}^{\prime}(s)\right) d s \\
& \leq \varphi\left(x_{\alpha}\left(t_{\alpha}\right)\right)+\int_{t_{\alpha}}^{t}\left(f(s)-\alpha x_{\alpha}(s)-x_{\alpha}^{\prime}(s), x_{\alpha}^{\prime}(s)\right) d s \\
& \leq C_{6}\left(x_{0}, T,\|f\|_{L^{2}(] 0, T[; H)}\right), \quad 0<\alpha<1 .
\end{aligned}
$$

On the other hand, by writing $\varphi\left(x_{\alpha}(t)\right) \geq \varphi\left(x_{0}\right)+\left(\partial \varphi\left(x_{0}\right), x_{\alpha}(t)-x_{0}\right), 0 \leq t \leq$ $T, \alpha>0$ we deduce that $\varphi\left(x_{\alpha}(t)\right)$ is also bounded from below so that finally $\left(\varphi \circ x_{\alpha}\right)_{0<\alpha<1}$ is bounded in $L^{\infty}(] 0, T[; H)$.

Now, using the second hypothesis of the theorem (every level subset is compact) we deduce that $x_{\alpha}(0) \rightarrow x(0)$ when $\alpha$ goes to 0 (at least for a subsequence $\left.\alpha_{n} \searrow 0\right)$. In fact we can easily check that $x_{\alpha}$ converges uniformly to $x$ on $[0, T]$ since

$$
\left\|x_{\alpha}(t)-x_{\beta}(t)\right\| \leq\left\|x_{\alpha}(0)-x_{\beta}(0)\right\|+|\alpha-\beta| \cdot T \cdot \sup _{0<\gamma<1}\left\|x_{\gamma}\right\|_{L^{\infty}(\mathrm{j} 0, T[; H)}
$$

for $0 \leq t \leq T, 0<\alpha, \beta<1$. Now, since $\lim _{\alpha \backslash 0} d x_{\alpha} / d t=d x / d t$ in the sense of $H$-valued vectorial distribution on $] 0, T\left[\right.$ and $\left(x_{\alpha}^{\prime}\right)_{\alpha>0}$ is bounded in $L^{2}(] 0, T[; H)$ it follows that $x^{\prime}$ belongs to $L^{2}(] 0, T[; H)$ and in particular $x$ is absolutely continuous on every compact of $] 0, T$ [ and therefore a.e. differentiable on $] 0, T$ [.

To complete the proof we need to show that $x(t) \in D(\varphi)$ a.e. on $] 0, T[$ and $x^{\prime}(t)+\partial \varphi x(t) \ni f(t)$ a.e. on $] 0, T[$. For arbitrarily $[u, v] \in \partial \varphi$ we have
$\frac{1}{2} e^{2 \alpha t}\left\|x_{\alpha}(t)-u\right\|^{2} \leq \frac{1}{2} e^{2 \alpha s}\left\|x_{\alpha}(s)-u\right\|^{2}+\int_{s}^{t} e^{2 \alpha \tau}\left(f(\tau)-\alpha u-v, x_{\alpha}(\tau)-u\right) d \tau$,
with $0 \leq s \leq t \leq T, \alpha>0$. Passing to the limit for $\alpha \searrow 0$ we get

$$
\frac{1}{2}\|x(t)-u\|^{2} \leq \frac{1}{2}\|x(s)-u\|^{2}+\int_{s}^{t}(f(\tau)-v, x(\tau)-u) d \tau, \quad 0 \leq s \leq t \leq T
$$

Thus

$$
(x(t)-x(s), x(s)-u) \leq \frac{1}{2}\|x(t)-u\|^{2}-\frac{1}{2}\|x(s)-u\|^{2} \leq \int_{s}^{t}(f(\tau)-v, x(\tau)-u) d \tau
$$

for $0 \leq s \leq t \leq T$. Since $x$ is a.e. differentiable on $] 0, T$ [ we find that

$$
\begin{aligned}
\left(x^{\prime}(t), x(t)-u\right) & =\lim _{s \nearrow t} \frac{1}{t-s}(x(t)-x(s), x(s)-u) \\
& \leq \lim _{s \nearrow t} \frac{1}{t-s} \int_{s}^{t}(f(\tau)-v, x(\tau)-u) d \tau \\
& =(f(t)-v, x(t)-u), \quad \text { a.e. } t \in] 0, T[, \forall[u, v] \in \partial \varphi
\end{aligned}
$$

Finally, since $\partial \varphi$ is maximal monotone and $\left(f(t)-x^{\prime}(t)-v, x(t)-u\right) \geq 0$ for all $[u, v] \in \partial \varphi$ we deduce that $x(t) \in D(\partial \varphi)$ a.e. on $] 0, T\left[\right.$ and $x^{\prime}(t)+\partial \varphi x(t) \ni f(t)$ a.e. on $] 0, T$. Since $\varphi$ is lower-semicontinuous we also have

$$
\varphi(x(t)) \leq \lim _{\alpha \searrow 0} \inf \varphi\left(x_{\alpha}(t)\right) \leq \lim _{\alpha \searrow 0} \inf \left\|\varphi \circ x_{\alpha}\right\|_{L^{\infty}} \leq \sup _{0<\gamma<1}\left\|\varphi \circ x_{\gamma}\right\|_{L^{\infty}}
$$

As previous, by writing

$$
\begin{aligned}
\varphi(x(t)) & \geq \varphi\left(x_{0}\right)+\left(\partial \varphi\left(x_{0}\right), x(t)-x_{0}\right) \\
& \geq \varphi\left(x_{0}\right)-\left\|\partial \varphi\left(x_{0}\right)\right\| \cdot\left(\left\|x_{0}\right\|+\lim _{\alpha \searrow 0} \inf \left\|x_{\alpha}(t)\right\|\right) \\
& \geq \varphi\left(x_{0}\right)-\left\|\partial \varphi\left(x_{0}\right)\right\| \cdot\left(\left\|x_{0}\right\|+\sup _{0<\gamma<1}\left\|x_{\gamma}\right\|_{L^{\infty}}\right), \quad 0 \leq t \leq T
\end{aligned}
$$

we deduce finally that $\varphi \circ x \in L^{\infty}(0, T)$.

Remark 3.17 If $\operatorname{dim} H<+\infty$ then the level subsets $\left\{x \in H ; \varphi(x)+\|x\|^{2} \leq\right.$ $M\}$ are compact as bounded sets.

Remark 3.18 Assume that $\varphi: H \rightarrow]-\infty,+\infty]$ is a lower-semicontinuous proper convex function such that Range $(\partial \varphi)=H$ which is equivalent to

$$
\lim _{\|x\| \rightarrow \infty}\{\varphi(x)-(x, y)\}=+\infty, \quad \forall y \in H
$$

see [4], pp.41. In particular, by taking $y=\langle f\rangle$ we deduce that the hypothesis (62) is verified.

Remark 3.19 Assume that $\varphi$ is coercive

$$
\lim _{\|x\| \rightarrow \infty} \frac{\left(\partial \varphi(x), x-x_{0}\right)}{\|x\|}=+\infty, \quad \forall x_{0} \in D(\varphi)
$$

which is equivalent to $\lim _{\|x\| \rightarrow \infty} \frac{\varphi(x)}{\|x\|}=+\infty$ (see [4], pp.42). Then $\operatorname{Range}(\varphi)=$ $H$ because the previous condition is satisfied: $\lim _{\|x\| \rightarrow \infty}\{\varphi(x)-(x, y)\}=+\infty$, for all $y \in H$ and therefore (62) is verified.

Theorem 3.20 Suppose that $\varphi: H \rightarrow]-\infty,+\infty]$ is a lower-semicontinuous proper convex function and $f \in W^{1,1}(] 0, T[; H)$ such that

$$
\begin{equation*}
\lim _{\|x\| \rightarrow \infty}\{\varphi(x)-(x,\langle f\rangle)\}=+\infty \tag{71}
\end{equation*}
$$

and every level subset $\left\{x \in H ; \varphi(x)+\|x\|^{2} \leq M\right\}$ is compact. Then equation (61) has T-periodic solutions $x \in C([0, T] ; H) \cap W^{1, \infty}(] 0, T[; H)$ which satisfy

$$
x(t) \in D(\partial \varphi), \quad \forall t \in[0, T], \quad \frac{d^{+}}{d t} x(t)+(\partial \varphi x(t)-f(t))^{\circ}=0, \quad \forall t \in[0, T]
$$

where $(\partial \varphi-f)^{\circ}$ denote the minimal section of $\partial \varphi-f$.
Proof Since $W^{1,1}(] 0, T[; H) \subset L^{2}(] 0, T[; H)$ the previous theorem applies. Consider $x \in C([0, T] ; H) \cap W^{1,2}(] 0, T[; H)$ a $T$-periodic solution for (61). Since $\left\|x^{\prime}\right\|_{L^{2}(] 0, T[; H)} \leq\|f\|_{L^{2}(] 0, T[; H)}$ it follows that there is $\left.t^{\star} \in\right] 0, T[$ such that $x$ is differentiable in $t^{\star}$ and $\left\|x^{\prime}\left(t^{\star}\right)\right\| \leq \frac{1}{\sqrt{T}}\|f\|_{L^{2}(] 0, T[; H)}$. By standard calculation we find that:

$$
\left\|\frac{1}{h}(x(t+h)-x(t))\right\| \leq\left\|\frac{1}{h}\left(x\left(t^{\star}+h\right)-x\left(t^{\star}\right)\right)\right\|+\int_{t^{\star}}^{t} \| \frac{1}{h}(f(\tau+h)-f(\tau) \| d \tau
$$

and therefore $\sup _{0 \leq t \leq T, h>0}\left\|\frac{1}{h}(x(t+h)-x(t))\right\| \leq C$ which implies that $x \in$ $W^{1, \infty}(] 0, T[; H)$. Making use of the inequality
$\frac{1}{h}(x(t+h)-x(t), x(t)-u) \leq \frac{1}{h} \int_{t}^{t+h}(f(\tau)-v, x(\tau)-u) d \tau, \quad 0 \leq t<t+h \leq T$,
which holds for every $[u, v] \in \partial \varphi$ we deduce that $x(t) \in D(\partial \varphi)$ for all $t \in$ $[0, T]$ and the weak closure of the set $\left\{\frac{1}{h}(x(t+h)-x(t)), h>0\right\}$ belongs to $f(t)-\partial \varphi x(t), \forall t \in[0, T]$. On the other hand by writing

$$
\|x(t+h)-u\| \leq\|x(t)-u\|+\int_{t}^{t+h}\|f(\tau)-v\| d \tau, \quad 0 \leq t<t+h \leq T
$$

for $u=x(t)$ and $v \in \partial \varphi x(t)$ we find that

$$
\begin{aligned}
\left\|(\partial \varphi x(t)-f(t))^{\circ}\right\| & \leq\left\|w-\lim _{h \searrow 0} \frac{1}{h}(x(t+h)-x(t))\right\| \\
& \leq \limsup _{h \searrow 0}\left\|\frac{1}{h}(x(t+h)-x(t))\right\| \\
& \leq\left\|(\partial \varphi x(t)-f(t))^{\circ}\right\| .
\end{aligned}
$$

This shows that $\lim _{h \backslash 0} \frac{1}{h}(x(t+h)-x(t))=\frac{d^{+}}{d t} x(t)$ exists for every $t \in[0, T]$ and coincides with $-(\partial \varphi x(t)-f(t))^{\circ}$.
