Динамические уравнения для спиновой цепочки в пространстве $SU(2S+1)/SU(2S) \cdot U(1)$ и легкоосный магнетик со спином

Построены гамильтоновы уравнения в пространстве $SU(2S+1)/SU(2S) \cdot U(1)$ для полуклассических моделей магнетиков с произвольным спином. Исследован магнетик Гейзенберга со спином $S = 3/2$ при помощи обобщенных когерентных состояний группы $SU(4)$. Показано, что классические вакуум-системы лежат в $SU(2)$ сечении 6-мерного спинового фазового пространства CP^3 . Найдены две дополнительные высокочастотные моды в магнонном спектре легкоосного магнетика.

Работа выполнена в Лаборатории вычислительной техники и автоматизации ОИЯИ.

Dynamical Equations for Spin Chain in the $SU(2S+1)/SU(2S) \cdot U(1)$ Space and $S = 3/2$ Easy Axis Magnet

The Hamiltonian equations of motion in the $SU(2S+1)/SU(2S) \cdot U(1)$ space for semiclassical models of magnets with arbitrary spins are constructed. The $S = 3/2$ Heisenberg magnet is investigated by use of the generalized coherent states of $SU(4)$ group. We show that classical vacuum of system lie in the $SU(2)$ section of total 6-dimensional spin phase space CP^3 . Two additional high frequency modes are found in magnon spectrum of the easy-axis magnet.

The investigation has been performed at the Laboratory of Computing Techniques and Automation, JINR.

Communication of the Joint Institute for Nuclear Research. Dubna 1991

A great attention was recently paid to theoretical study and experimental investigations of the $S=1$ magnets. There only three spin states exist in every site of crystall lattice and all possible transitions between these states are described by eight independent operators of the $SU(3)$ group. The main problem in general case (arbitrary spins) is to construct correctly Hamiltonian equations of motion in the corresponding $SU(2S+1)/SU(2) \otimes U(1)$ space of the $SU(2S+1)$ group. Such equations in the $SU(3)/SU(2) \otimes U(1)$ space were derived in paper [4].

Here we come to more general problem i.e. to derive Hamiltonian equations of motion in the $SU(3)/SU(2) \otimes U(1)$ space. As a concrete example the spin $S=3/2$ Heisenberg magnet is considered.

Note, that in the $S=3/2$ case all possible transition between four spin states in every site are described by fifteen independent operators of the $SU(4)$ group. This operators are related by linear quadratic and cubic combinations of spin operators.

Dimension of spin state space for spin $S=3/2$, is

$$\dim H = 6. \quad (1)$$

The symmetrical space

$$CP^2 = SU(4)/SU(3) \otimes U(1) \quad (2)$$

has the same dimension.

In the paper [3] the generalized spin coherent states

are constructed to give for the SU(4) group

$$|\Psi\rangle = \exp \left\{ \sum_{i=1}^3 \left(\xi_i \hat{T}_i^+ - \bar{\xi}_i \hat{T}_i^- \right) \right\} \quad (3)$$

where generators \hat{T}_i^{\pm} are defined by the formulae

$$\hat{T}_1^+ = \begin{pmatrix} 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 1 \\ 0 & 0 & 0 & 0 \end{pmatrix}, \quad \hat{T}_1^- = \begin{pmatrix} 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \\ 0 & 0 & 1 & 0 \end{pmatrix},$$

$$\hat{T}_2^+ = \begin{pmatrix} 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 1 \\ 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \end{pmatrix}, \quad \hat{T}_2^- = \begin{pmatrix} 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 \end{pmatrix},$$

$$\hat{T}_3^+ = \begin{pmatrix} 0 & 0 & 0 & 1 \\ 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \end{pmatrix}, \quad \hat{T}_3^- = \begin{pmatrix} 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \\ 1 & 0 & 0 & 0 \end{pmatrix}.$$

Corresponding coherent state for spin $S=3/2$ in the SU(4)/SU(3)⊗U(1) space assumes the form

$$|\Psi\rangle = \left(1 + |\Psi_1|^2 + |\Psi_2|^2 + |\Psi_3|^2 \right)^{-1/2} \left\{ |0\rangle + \Psi_1 |1\rangle + \Psi_2 |2\rangle + \Psi_3 |3\rangle \right\} \quad (4)$$

where

$$\Psi_1 = \frac{\xi_1}{|\xi|} \tan|\xi|, \quad |\xi|^2 = |\xi_1|^2 + |\xi_2|^2 + |\xi_3|^2.$$

As spin operators for $S=3/2$ we choose the following operators

$$\hat{S}^+ = \begin{pmatrix} 0\sqrt{3} & 0 & 0 \\ 0 & 0 & 2 & 0 \\ 0 & 0 & 0\sqrt{3} & 0 \\ 0 & 0 & 0 & 0 \end{pmatrix}, \quad \hat{S}^- = \begin{pmatrix} 0 & 0 & 0 & 0 \\ \sqrt{3} & 0 & 0 & 0 \\ 0 & 2 & 0 & 0 \\ 0 & 0\sqrt{3} & 0 & 0 \end{pmatrix}, \quad \hat{S}^z = \frac{1}{2} \begin{pmatrix} 3 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & -1 & 0 \\ 0 & 0 & 0 & -3 \end{pmatrix}, \quad (5)$$

$$\text{where } \hat{S}^x = \frac{1}{2} (\hat{S}^+ + \hat{S}^-), \quad \hat{S}^y = \frac{1}{2i} (\hat{S}^+ - \hat{S}^-),$$

that satisfy the commutation relations of the SU(2) algebra

$$[\hat{S}^+, \hat{S}^-] = 2\hat{S}^z, \quad [\hat{S}^z, \hat{S}^+] = \hat{S}^+, \quad [\hat{S}^z, \hat{S}^-] = -\hat{S}^-.$$

Remaining generators of the SU(4) group can be taken as quadratic and cubic combinations of spin operators.

Averaging the spin operators via generalized coherent state (GCS) (4) we have

$$\begin{aligned} \langle \hat{S}^+ \rangle &= \frac{\sqrt{3}\bar{\Psi}_2\bar{\Psi}_3 + 2\Psi_1\bar{\Psi}_2 + \sqrt{3}\bar{\Psi}_1}{1 + |\Psi_1|^2 + |\Psi_2|^2 + |\Psi_3|^2}, \\ \langle \hat{S}^- \rangle &= \frac{\sqrt{3}\bar{\Psi}_2\Psi_3 + 2\bar{\Psi}_1\Psi_2 + \sqrt{3}\Psi_1}{1 + |\Psi_1|^2 + |\Psi_2|^2 + |\Psi_3|^2}, \\ \langle \hat{S}^z \rangle &= \frac{3|\Psi_3|^2 + |\Psi_2|^2 - |\Psi_1|^2 - 3}{2(1 + |\Psi_1|^2 + |\Psi_2|^2 + |\Psi_3|^2)}. \end{aligned} \quad (7)$$

We also give double correlators that will be of use in what follow

$$\begin{aligned} \langle \hat{S}^z \hat{S}^z \rangle &= \frac{N}{4} (9|\Psi_3|^2 + |\Psi_2|^2 + |\Psi_1|^2 + 9), \\ \langle \hat{S}^+ \hat{S}^+ \rangle &= 2\sqrt{3}(\Psi_1\bar{\Psi}_3 + \bar{\Psi}_2), \\ \langle \hat{S}^- \hat{S}^- \rangle &= 2\sqrt{3}(\bar{\Psi}_1\Psi_3 + \Psi_2), \\ \langle \hat{S}^+ \hat{S}^- \rangle &= N(3|\Psi_3|^2 + 4|\Psi_2|^2 + 3|\Psi_1|^2), \end{aligned} \quad (8)$$

$$\langle \hat{S}^+ \hat{S}^z \rangle = \frac{N}{2} \sqrt{3} (\Psi_2 \bar{\Psi}_3 - 2\Psi_1 \bar{\Psi}_2 - 3\sqrt{3}\Psi_1),$$

$$\langle \hat{S}^z \hat{S}^- \rangle = \overline{\langle \hat{S}^+ \hat{S}^z \rangle},$$

where

$$N = 1 / (1 + |\Psi_1|^2 + |\Psi_2|^2 + |\Psi_3|^2).$$

Hence, the Casimir operator is

$$\langle \hat{C} \rangle = \frac{1}{2} \left(\langle \hat{S}^+ \hat{S}^- \rangle + \langle \hat{S}^- \hat{S}^+ \rangle \right) + \langle \hat{S}^z \hat{S}^z \rangle = \frac{15}{4}. \quad (9)$$

Contrary to the SU(3) GCS the conservation law $s^2 = \text{const}$ and even $s^2 + q^2 = \text{const}$ are now broken, and the identity

$$s^2 + q^2 + f^2 = 1 \quad (10)$$

is valid, where q^2 and f^2 are the corresponding sums of double and triple correlators.

Whence in order to obtain dynamical equations we construct the Lagrangian following to paper [6]

$$L = i\hbar \frac{\dot{\Psi}_1 \bar{\Psi}_1 - \Psi_1 \dot{\bar{\Psi}}_1 + \dot{\Psi}_2 \bar{\Psi}_2 - \Psi_2 \dot{\bar{\Psi}}_2 + \dot{\Psi}_3 \bar{\Psi}_3 - \Psi_3 \dot{\bar{\Psi}}_3}{1 + |\Psi_1|^2 + |\Psi_2|^2 + |\Psi_3|^2} - H(\Psi_1, \Psi_2, \Psi_3). \quad (11)$$

Varying Lagrangian (11) we get the following equations in the SU(4)/SU(3)⊗U(1) space

$$i\dot{\Psi}_1 = \left(1 + |\Psi_1|^2 + |\Psi_2|^2 + |\Psi_3|^2\right) \left[(1 + |\Psi_1|^2) \frac{\delta H}{\delta \bar{\Psi}_1} + \Psi_1 \bar{\Psi}_2 \frac{\delta H}{\delta \bar{\Psi}_2} + \Psi_1 \bar{\Psi}_3 \frac{\delta H}{\delta \bar{\Psi}_3} \right]$$

$$i\dot{\Psi}_2 = \left(1 + |\Psi_1|^2 + |\Psi_2|^2 + |\Psi_3|^2\right) \left[(1 + |\Psi_2|^2) \frac{\delta H}{\delta \bar{\Psi}_2} + \Psi_2 \bar{\Psi}_1 \frac{\delta H}{\delta \bar{\Psi}_1} + \Psi_2 \bar{\Psi}_3 \frac{\delta H}{\delta \bar{\Psi}_3} \right]$$

$$i\dot{\Psi}_3 = \left(1 + |\Psi_1|^2 + |\Psi_2|^2 + |\Psi_3|^2\right) \left[(1 + |\Psi_3|^2) \frac{\delta H}{\delta \bar{\Psi}_3} + \Psi_3 \bar{\Psi}_1 \frac{\delta H}{\delta \bar{\Psi}_1} + \Psi_3 \bar{\Psi}_2 \frac{\delta H}{\delta \bar{\Psi}_2} \right].$$

Analogous equations one can get for the conjugate functions $\bar{\Psi}_1, \bar{\Psi}_2, \bar{\Psi}_3$. One can now extend result (12) to the case of an arbitrary spins in the space SU(2S+1)/SU(2S)⊗U(1) to obtain

$$i\dot{\Psi}_1 = \left(1 + \sum_{k=1}^n |\Psi_k|^2\right) \left[(1 + |\Psi_1|^2) \frac{\delta H}{\delta \bar{\Psi}_1} + \sum_{k=1}^n \Psi_1 \bar{\Psi}_k \frac{\delta H}{\delta \bar{\Psi}_k} \alpha_{1k} \right] \quad (13)$$

where

$$\alpha_{1k} = \begin{cases} 0, & l=k \\ 1, & l \neq k. \end{cases}$$

Let us now compare coherent states for spin S=3/2 in the SU(4) version with that in the SU(3) one. GCS for S=3/2 in the SU(2) version (see [7]) has the form

$$|\eta\rangle = \left(1 + |\eta|^2\right)^{-1/2} \left\{ |0\rangle + \sqrt{3}\eta |1\rangle + \sqrt{3}\eta^2 |2\rangle + \eta^3 |3\rangle \right\} \quad (14)$$

and in the SU(4) version

$$|\Psi\rangle = \left(1 + |\Psi_1|^2 + |\Psi_2|^2 + |\Psi_3|^2\right)^{-1/2} \left\{ |0\rangle + \Psi_1 |1\rangle + \Psi_2 |2\rangle + \Psi_3 |3\rangle \right\}.$$

The states $|\eta\rangle$ are defined by the points of sphere S^2 and the state $|\Psi\rangle$ by points of $\mathbb{C}P^3$. Quantum system with the spin S=3/2 lives in the 6-dimensional state space and the Hamiltonian averaged over the SU(2)/U(1) describes its behaviour in a two-dimensional section of this space. It is easy to check that this section is

$$\Psi_3 = \frac{1}{3\sqrt{3}} \Psi_1^3, \quad \Psi_2 = \frac{1}{\sqrt{3}} \Psi_1^2, \quad \Psi_3 = \sqrt{3} \Psi_1^3. \quad (15)$$

Hereafter we investigate S=3/2 spin chain that describes the ferromagnet with uni-axis exchange anisotropy. As usual, Hamiltonian is given by

$$\hat{H} = -J \sum \hat{S}_j^z \hat{S}_{j+1}^z - \delta \sum \hat{S}_j^z \hat{S}_{j+1}^z. \quad (16)$$

In the continuum limit, we get the classical Hamiltonian

$$H = -J \int \left\{ \langle \hat{S}^+ \rangle \langle \hat{S}^- \rangle + (1+\delta) (\langle \hat{S}^z \rangle)^2 - \frac{a_0^2}{2} \left(\langle \hat{S}^+ \rangle_x \langle \hat{S}^- \rangle_x + (1+\delta) (\langle \hat{S}^z \rangle_x)^2 \right) \right\} dx.$$

Let us calculate classical vacuum states of this Hamiltonian. In the case $\delta > 0$, that corresponds to the "easy axis" model of ferromagnet, the ground state is

$$\Psi_1 = \Psi_2 = \Psi_3 = 0.$$

that is terms of GCS $|\Psi_0\rangle = |0\rangle$, which coincides with the ground states of SU(2) and SU(3) versions (see [3]). When $\delta < 0$, the "easy plane" model, Hamiltonian acquires its minimum at $\Psi_1 = \Psi_2 = \sqrt{3}$ and $\Psi_3 = 1$ and GCS takes the form $|\Psi_0\rangle = \sqrt{8}(|0\rangle + \sqrt{3}|1\rangle + \sqrt{3}|2\rangle + |3\rangle)$, that is also the same as in the SU(2) version for spin $S=3/2$.

Now we derive dispersions for linear waves propagating in the system. In order to do this we expand Hamiltonian (17) near the easy-axis ground state and keeping the second order terms we get

$$H = -\frac{3}{2} J \int \left\{ 3|\Psi_1|^2 - |\Psi_2|^2 - 3|\Psi_3|^2 + \delta (|\Psi_1|^2 + |\Psi_2|^2 + |\Psi_3|^2) - a_0^2 |\Psi_{1x}|^2 \right\} \frac{dx}{a_0}.$$

Linearized equations have the form

$$i\dot{\Psi}_1 = -(3 + \delta)\Psi_1 - \Psi_{1xx},$$

$$i\dot{\Psi}_2 = (\delta + 1)\Psi_2,$$

$$i\dot{\Psi}_3 = 3(\delta + 1)\Psi_3.$$

Hence the dispersion relations are

$$\omega_1 = k^2 - (3 + \delta), \quad (19)$$

$$\omega_2 = \delta + 1, \quad (20)$$

$$\omega_3 = 3(\delta + 1). \quad (21)$$

Thus, in the linear approximation there is a low frequency

mode in the $S=3/2$ easy-axis magnet, with dispersion formula (19) being the same to that of the SU(2) model [3], and unlike $S=1$ magnet there are two additional high frequency modes (20) and (21). In the spin state space l. f. branch lie in the SU(2) section of the total 6-dimensional spin phase space, and h. f. branches span all the rest phase space.
