Фазовая фуикция в ядерно-ядерном рассеянии
Рязвит метол суммирования эйконального ряла как для амплитуд уиругого $A_{1} A_{2}$-расселния, так и для важных физических харектеристик некоторых неупругих процессов $A_{1} A_{2}$-взанмолейстьия. Получепы замкнутые ныражения для этих амплитуд, удобные длл проведения численних расчетов. В качестве примера привопится расчет для фазы и поправки к ней.

Работа выполнена в Лаборатории ядерных проблем ОИЯИ.

The Phase Functions in the Nucleus-Nucleus Scattering at High Energies
The method is developed for the summation of eikonal series for amplitudes of elastic $\mathrm{A}_{1} \mathrm{~A}_{2}-$ scattering as well as for important characteristics of some inelastic processes in $A_{1} A_{2}$ interactions. The close expressions, convenient for numerical calculations, are derived for these amplitudes. As an example, we present a calculation of the phase function and corrections to it.

The investigation has been performed at the Laboratory of Nuclear Problems, JINR,

Preprint of the Joint Institute for Nuclear Research

## I. INTRODUCTION

Many papers have been devoted to the theoretical analysis of the nucleus-nucleus (below $\mathrm{A}_{1} \mathrm{~A}_{2}$ ) elastic scattering processes in the eikonal approximation ${ }^{1 /}$. The paper of I.V.Andreev ${ }^{/ 2 /}$, where more or less completed and closed expressions have been obtained for the numerical calculation of the $A_{1} A_{2}$ elastic scattering amplitude, pleasantly differs from others. However inelastic $A_{1} A_{2}$ reactions have not so far been considered in the rigorous eikonal theory.

The aim of this paper and the following publications is to develop the eikonal expansion summation method, which allows one to obtain completed expressions both for the $A_{1} A_{2}$ elastic scattering amplitude and for the important physical characteristics of some $A_{1} A_{2}$ inelastic processes. In particular, the excitation processes of one and both incident nuclei, the elastic and the quasielastic charge exchange reactions and the quasielastic scattering are considered.

The Coulomb scattering problem in the $A_{2} A_{2}$ interaction is described. The main results of ref $/ 2 /$ as intermediate calculation are presented.

## II. RELATION BETWEEN THE AMPLITUDES OF THE NUCLEUS-NUCLEUS SCATTERING WITH CORRELATED AND UNCORRELATED NUCLEON DISTRIBUTIONS

We use well-known relation of the eikonal theory, which connects the $A_{1} A_{2}$ scattering amplitude with the
nucleon-nucleon scattering one and the ground state wave functions $\Psi_{\mathrm{A}_{1}}, \Psi_{\mathrm{A}_{2}}$ of the colliding nuclei:

$$
\begin{align*}
& \mathrm{F}_{\mathrm{A}_{1} \mathrm{~A}_{2}}(\mathrm{q})=\frac{i p}{2 \pi} \int \mathrm{~d}^{2} \mathrm{~b} \exp (\mathrm{iqb}) \Gamma_{A_{1} A_{2}}(\mathrm{~b}) \\
& \left.\Gamma_{\mathrm{A}_{1} \mathrm{~A}_{2}}(\mathrm{~b})=1-\ll \prod_{\mathrm{i}=1}^{\mathrm{A}_{1}}{ }_{1 \mathrm{k}=1}^{\mathrm{A}_{2}}\left[1-\gamma\left(\mathrm{b}-\mathrm{s}_{\mathrm{i}}-\tilde{\mathrm{s}}_{\mathrm{k}}\right)\right]\right\rangle{ }_{\mathrm{A}_{1}}>{ }_{\mathrm{A}_{2}} \\
& \left.\left.\ll 0\left(s_{i}, \tilde{s}_{k}\right)\right\rangle{ }_{A_{1}}\right\rangle_{A_{2}}=\int \prod_{i=1}^{A_{1}}{ }^{1} \mathrm{dr}_{i}\left|\Psi_{A_{1}}\left(r_{1}, \ldots, r_{A_{1}}\right)\right|^{2} * \\
& * \int \prod_{\mathrm{k}=1}^{\mathrm{A}_{2}} \mathrm{~d} \tilde{r}_{\mathrm{k}}\left|\mathbb{I}_{\mathrm{A}_{2}}\left(\tilde{\mathrm{r}}_{1}, \ldots, \tilde{\mathrm{r}}_{\mathrm{A}_{2}}\right)\right|^{2} 0\left(\mathrm{~s}_{\mathrm{i}}, \tilde{s}_{\mathrm{k}}\right)  \tag{1}\\
& r_{i}=\left\{\mathrm{s}_{\mathrm{i}}, \mathrm{z}_{\mathrm{i}}\right\}, \quad \tilde{\mathrm{r}}_{\mathrm{k}}=\left\{\tilde{\mathrm{s}}_{\mathrm{k}}, \tilde{z}_{\mathrm{k}}\right\} \\
& \gamma(b)=\frac{1}{2 \pi i p} \int f_{N N}(q) e^{-i q b} d^{2} q \quad .
\end{align*}
$$

We use the usual representation for the squared nucleus wave function $A_{1(2)}$ in the expansion form

$$
\begin{aligned}
& \left|\Psi_{A_{1(2)}}\left(r_{1}, \ldots, r_{A_{1(2)}}\right)\right|^{2}=\prod_{i=1}^{A_{1(2)}} \rho_{1(2)}\left(r_{i}\right)+ \\
& +\sum_{i \neq k}^{A} C_{1(2)}^{(2)}\left(r_{j}, r_{k}\right) \prod_{\ell \neq i, k}^{A} \rho_{1(2)}\left(r_{\ell}\right)+
\end{aligned}
$$

where $\rho(r)$ is the so-called one-body density, $C_{1(2)}^{(2)}$ $C_{1(2)}^{(3)}$ and so on are the second, third and higher order correlation functions*.

[^0] is taken into account in a usual way $/ 1 /$.

One introduces the thickness functions $T_{1}(s) \quad, T_{2}(\tilde{s})$ by the usual relation

$$
\begin{equation*}
\mathrm{T}_{1(2)}(\mathrm{s})=\mathrm{A}_{1(2)} \int \rho_{1(2)}(\mathrm{s}, \mathrm{z}) \mathrm{d} z \tag{3}
\end{equation*}
$$

It is obvious that the profile function $\Gamma_{\mathrm{A}_{1} \mathrm{~A}_{2}}^{(0)}(\mathrm{b})$ is
the functional only of the thickness functions ${ }^{\prime} \Gamma_{1}, \mathrm{~T}_{2}$ and the nucleon-nucleon profile function $\gamma$ in the uncorrelated nucleon distribution ( $\mathrm{C}_{1(2)}-0$ ) approximation for the colliding nuclei

$$
\Gamma_{\mathrm{A}_{1} \mathrm{~A}_{2}}^{(0)}(\mathrm{b})=\Gamma_{\mathrm{A}_{1} \mathrm{~A}_{2}}^{(0)}\left\{\mathrm{T}_{1}, \mathrm{~T}_{2}, \gamma\right\}
$$

By executing accurate averaging over the uncorrelated nucleon distribution of nuclei $A_{1}$ in relation (1) we obtain

$$
\begin{equation*}
\Gamma_{\mathrm{A}_{1} \mathrm{~A}_{2}}^{(0)}\left\{\mathrm{T}_{1}, \mathrm{~T}_{2}, \gamma\right\}=1-\left\langle 1-\frac{1}{\mathrm{~A}_{1}} \int \Gamma_{\mathrm{A}_{2}}(\mathrm{~b}-\mathrm{s},\{\tilde{\mathrm{~s}}\}) \mathrm{T}_{1}(\mathrm{~s})\right]^{\mathrm{A}_{1}}{ }_{\mathrm{A}_{2}} \tag{4}
\end{equation*}
$$

where

$$
\begin{aligned}
& \langle 0\{\tilde{\mathrm{~s}}\}\rangle_{\mathrm{A}_{2}}=\int \prod_{\mathrm{k}=1}^{\mathrm{A}_{2}}\left(\frac{\mathrm{~T}_{2}\left(\tilde{\mathrm{~s}}_{\mathrm{k}}\right)}{\mathrm{A}_{2}} \mathrm{~d} \tilde{\mathrm{~s}}_{\mathrm{k}}\right) 0\{\tilde{\mathrm{~s}}\} \\
& \left.\Gamma_{\mathrm{A}_{2}}(\mathrm{~b}-\mathrm{s}, \tilde{\mathrm{~s}}\}\right)=1-\prod_{\mathrm{k}=1}^{\mathrm{A}_{2}}\left[1-y\left(\mathrm{~b}-\mathrm{s}-\tilde{\mathrm{s}}_{\mathrm{k}}\right)\right]
\end{aligned}
$$

The consideration of the pair correlations in $A_{1}$ reduces to the correction term in the profile function

$$
\begin{align*}
& \Delta_{1}^{(2)} \Gamma_{\mathrm{A}_{1} \mathrm{~A}_{2}}=-\frac{\left(\mathrm{A}_{1}-1\right)}{2 \mathrm{~A}_{2}} \int \mathrm{C}_{1}^{(2)}\left(\mathrm{r}_{1}, \mathrm{r}_{2}\right) \mathrm{dr} \mathrm{~A}_{1} \mathrm{dr}{ }_{2} * \\
& *<\Gamma\left(\mathrm{b}-\mathrm{s}_{1},\{\tilde{\mathrm{~s}}\}\right) \Gamma\left(\mathrm{b}-\mathrm{s}_{2},\{\tilde{\mathrm{~s}}\}\right)\left[1-\frac{1}{\mathrm{~A}_{2}} \int \Gamma_{\mathrm{A}_{2}}(\mathrm{~b}-\mathrm{s},\{\tilde{\mathrm{~s}}\}) *\right.  \tag{5}\\
& \left.* \mathrm{~T}_{\mathrm{A}_{2}}\left(\left\{\tilde{\mathrm{~s}}_{2}\right\}\right)\right] \mathrm{A}_{2}-2 \\
& >\mathrm{A}_{2} \\
& \equiv-\frac{\mathrm{A}_{1}^{2}}{2!} \int \mathrm{C}_{1}^{(2)}\left(\mathrm{r}_{1}, \mathrm{r}_{2}\right) \frac{\delta^{2} \Gamma_{\mathrm{A}}^{(0)}{ }_{1} \mathrm{~A}_{2}\left\{\mathrm{~T}_{1}, \mathrm{~T}_{2}, \gamma\right\}}{\delta \mathrm{T}\left(\mathrm{~s}_{1}\right) \delta \mathrm{T}\left(\mathrm{~s}_{2}\right)} \mathrm{dr}_{1} \mathrm{dr}_{2} .
\end{align*}
$$

Similarly, the effect of the three-body correlation in the nucleus may be presented in the form

$$
\begin{equation*}
\Delta_{1}^{(3)} \Gamma_{\mathrm{A}_{1} \mathrm{~A}_{2}}=\frac{\mathrm{A}_{1}^{3}}{3!} \int \mathrm{C}_{1}^{(3)}\left(\mathrm{r}_{1}, \mathrm{r}_{2}, \mathrm{r}_{3}\right) \frac{\delta^{3} \Gamma_{\mathrm{A}_{1}}^{(0)} \mathrm{A}_{2}\left\{\mathrm{~T}_{1}, \mathrm{~T}_{2}, \gamma\right\}}{\delta \mathrm{T}\left(\mathrm{~s}_{1}\right)} \frac{\left.\delta \mathrm{T}\left(\mathrm{~s}_{2}\right) \delta \mathrm{T}_{3}\right)}{\mathrm{s}_{3}} \mathrm{dr}_{1} \mathrm{dr}_{2} \mathrm{dr}_{3} \tag{6}
\end{equation*}
$$

and so on.
Thus, if the concrete functional dependence $\Gamma_{A_{1}} A_{2}$ on $\mathrm{T}_{1}$ and $\mathrm{T}_{2}$ is known, the consideration of the nucleon correlation effects in the nuclei leads to a simple convolution operation of correlation functions together with the functional differentiation $\Gamma_{A_{1}}^{(0)} A_{2}$ over the thickness functions $\mathrm{T}_{1,2}$.

Such dependence is determined in the optical limit by the atomic number of both nuclei $\left(\mathrm{A}_{1}, \mathrm{~A}_{2} \rightarrow \infty\right)^{/ 2 \prime}$. However, the representation of this dependence in the double series form is not quite convenient for the practical employment. Below the closed formula for this series summation is obtained.

## III. TRANSITION TO THE OPTICAL LIMIT AND THE CORRECTION TO IT

So, the task to find $\Gamma^{(0)}\left(\mathrm{T}_{1}, \mathrm{~T}_{2}, \gamma\right)$ comes to the averaging of the binomial function $(1+X / A)^{A}$. It is known that the average value of any function $<\phi(X)\rangle$ can be expressed through the derivatives of this function $\phi^{\mathrm{n}}(0)$ and the $X_{n}$-central moments of the variable $X$

$$
\begin{aligned}
& X_{1}=\langle X\rangle \\
& X_{n}=\left\langle(X-\langle X\rangle)^{n}\right\rangle \quad n \geq 2
\end{aligned}
$$

One of the simplest expressions is that for the average value of $\exp (\mathrm{X})$

$$
\begin{align*}
& <\exp (X)>=\exp \left\{X_{1}+\frac{1}{2!} X_{2}+\frac{1}{3!} X_{3}+\frac{1}{4!}\left(X_{4}-3 X_{2}^{2}\right)+\right. \\
& \left.+\frac{1}{5!}\left(X_{5}-5 X_{2} X_{3}\right)+\ldots\right\} \tag{7}
\end{align*}
$$

Since at $A \gg 1$

$$
\left(1+\frac{X}{A}\right)^{A}=\exp (X)+0\left(\frac{1}{A}\right)
$$

the optical limit may be considered as the reasonable approximation in the case of heavy and intermediate nuclei and the atomic number must be taken into account as the correction of order $\frac{1}{\mathrm{~A}_{1(2)}}$, i.e.,

$$
\begin{equation*}
\left(1+\frac{X}{A}\right)^{A}=\left(1-\frac{X^{2}}{2} \frac{X^{3}}{3}+\frac{X^{3}}{3 A}-\cdots\right) \exp (X) \tag{8}
\end{equation*}
$$

Assuming that $X=-\int \Gamma^{\prime}(b-s,\{s\}) T_{1}(s) d s, \quad$ we obtain

$$
\left\langle\mathrm{X}^{\mathrm{n}} \exp (\mathrm{X})\right\rangle=\int \mathrm{T}_{1}\left(\mathrm{~s}_{1}\right) \ldots \mathrm{T}_{1}\left(\mathrm{~s}_{11}\right) \mathrm{ds}_{1} \ldots \mathrm{ds}_{\mathrm{n}} \frac{\delta^{\mathrm{n}}}{\delta \mathrm{~T}_{1}\left(\mathrm{~s}_{1}\right) \cdot \delta \mathrm{T}_{1}\left(\mathrm{~s}_{\mathrm{T}}\right)}<\exp (\mathrm{X}) \times(9)
$$

Thus, the calculation of correction terms of any order leads, essentially, to the functional $\left.\Gamma_{\mathrm{A}_{2}}^{(0)} \mathrm{A}_{1} \mathrm{~T}_{1}, \mathrm{~T}_{2}\right\}$

$$
\begin{align*}
\mathrm{I}_{\mathrm{A}_{2} \mathrm{~A}_{1}(\mathrm{opt})}^{\prime(0)}\left\{\mathrm{T}_{1}, \mathrm{~T}_{2}\right\} & =\lim _{\mathrm{A}_{2} \rightarrow \infty}\left[\left\langle 1-\exp \left(-\int \mathrm{I}_{\mathrm{A}_{2}}^{\prime}(\mathrm{b}-\mathrm{s},\{\tilde{\mathrm{~s}}\}) \mathrm{T}_{1}(\mathrm{~b}-\mathrm{s}) \mathrm{ds}\right)\right\rangle_{\mathrm{A}_{2}}\right]= \\
& =1-\exp \chi_{\mathrm{opt}}\left\{\mathrm{~T}_{1}, \mathrm{~T}_{2}\right\} . \tag{10}
\end{align*}
$$

The integration variable replacement $s \rightarrow b-s$ is produced in eq. (10).

Using the averaging rule of exponent (7) we obtain for the successive terms of expansion of the functional $\chi\left(\mathrm{T}_{1}, \mathrm{~T}_{2}\right)$ over the degree $\mathrm{T}_{1(2)}$ the following expressions

$$
\begin{align*}
& \mathrm{i}_{\chi}\left(\mathrm{T}_{1}, \mathrm{~T}_{2}\right)=\sum_{\mathrm{n}=1}^{\infty} \frac{1}{\mathrm{n}!} \chi_{\mathrm{n}}  \tag{11a}\\
& x_{1}=\int \mathrm{d}^{2} \mathrm{~S}_{1}(\mathrm{~T}-\mathrm{s})\left(\mathrm{E}_{1}(\mathrm{~s})-1\right)  \tag{11b}\\
& x_{2}=\int \mathrm{d}^{2} \mathrm{~s}_{1} \mathrm{~d}^{2} \mathrm{~s}_{2} \mathrm{~T}_{1}\left(\mathrm{~b}-\mathrm{s}_{1}\right) \mathrm{T}_{2}\left(\mathrm{~b}-\mathrm{s}_{2}\right)\left[\mathrm{E}_{2}\left(\mathrm{~s}_{1}, \mathrm{~s}_{2}\right)-\mathrm{E}_{1}\left(\mathrm{~s}_{1}\right) \mathrm{E}_{1}\left(\mathrm{~s}_{2}\right)\right] \\
& x_{3}=\int \mathrm{d}^{2} \mathrm{~s}_{1} \mathrm{~d}^{2} \mathrm{~s}_{2} \mathrm{~d}^{2} \mathrm{~s}_{3} \mathrm{~T}_{1}\left(\mathrm{~b}-\mathrm{s}_{1}\right) \mathrm{T}_{1}\left(\mathrm{~b}-\mathrm{s}_{2}\right) \mathrm{T}_{2}\left(\mathrm{~b}-\mathrm{s}_{3}\right) *  \tag{11c}\\
& *\left[\mathrm{E}_{3}\left(\mathrm{~s}_{1}, \mathrm{~s}_{2}, \mathrm{~s}_{3}\right)-\mathrm{E}_{2}\left(\mathrm{~s}_{1}, \mathrm{~s}_{2}\right) \mathrm{E}_{1}\left(\mathrm{~s}_{3}\right)-\mathrm{E}_{2}\left(\mathrm{~s}_{1}, \mathrm{~s}_{3}\right) \mathrm{E}_{1}\left(\mathrm{~s}_{2}\right)-\right. \\
& \left.\quad-\mathrm{E}_{2}\left(\mathrm{~s}_{2}, \mathrm{~s}_{3}\right) \mathrm{E}_{1}\left(\mathrm{~s}_{1}\right)+2 \mathrm{E}_{1}\left(\mathrm{~s}_{1}\right) \mathrm{E}_{1}\left(\mathrm{~s}_{2}\right) \mathrm{E}_{1}\left(\mathrm{~s}_{3}\right)\right] \tag{11d}
\end{align*}
$$

and so on, where

$$
\begin{aligned}
& \mathrm{D}_{\mathrm{n}}\left(\mathrm{~s}_{1}, \ldots . \mathrm{s}_{\mathrm{n}}\right)=\exp \left(\int \mathrm{d} \tilde{\mathrm{~s}} \mathrm{~T}_{2}(\tilde{s})\left\{\prod_{i=1}^{n}\left[1 \sim \gamma\left(\mathrm{~s}_{i}-\bar{s}\right)\right]-1\right\}\right) \\
& \text { Since the values } \chi_{n} \text { are formed of the combinations of }
\end{aligned}
$$ expressions of type $\Gamma_{A_{1}}^{(0)} A_{2}\left(A_{1}=\infty, A_{2}=1,2, \ldots n\right)$, the problem seems to be reduced to the initial. However, this is not so.

The structure of those combinations is such that integrands in (11b), (11d), as functions of relative variables $s_{i}-s_{p}, s_{i}-\tilde{s}$, substantially differ from zero only in the limits of nucleon-nucleon interaction radius $\mathrm{r}_{0}$. It is not difficult to be convinced of it expanding the values $E_{k}\left(s_{1} \ldots, s_{k}\right)$ in series by magnitudes of type $\int \ddot{\mathrm{ds}} \mathrm{T}_{2}(\underset{\mathrm{~s}}{ }) \prod_{\mathrm{i}=1}^{\mathrm{k}} \gamma\left(\tilde{\mathrm{s}}-\mathrm{s}_{\mathrm{i}}\right) \quad \mathrm{k} \geq 2$ and considering the $\delta$-like
behaviour of the profile function $\gamma$ in comparison with smooth change of thickness functions $T_{1}$ and $T_{2}$, if $r_{0}^{2} / R^{2}\left(A_{1(2)}\right)<1$ ( $R$ is the radius of nuclei), that is practically always satisfied. Taking into account the normalization

$$
\int y(\mathrm{~s}) \mathrm{ds}=\frac{\bar{\sigma}}{2}, \quad \bar{\sigma}=\sigma_{\mathrm{NN}}^{\mathrm{tot}}\left(1-\mathrm{i} \frac{\operatorname{Ref}(0)}{\operatorname{Imf}(0)}\right)
$$

we write $\gamma(\mathrm{s})$ in the form

$$
\begin{align*}
& \gamma(\mathrm{s})=\frac{\tilde{\sigma}}{2} \tilde{\delta}(\mathrm{~s}) \\
& \tilde{\delta}(\mathrm{s})=\frac{-1}{\pi r_{0}^{2}} \Phi\left(\frac{\mathrm{~s}^{2}}{\mathrm{n}^{2}}\right) \quad \int_{0}^{\infty} \Phi(\mathrm{X}) \mathrm{dX}=1 \tag{12}
\end{align*}
$$

$\Phi(\mathrm{X}) \ll 1$ at $\mathrm{X} \gg 1$.
The concrete form of $\Phi(X)$ is determined by the q-dependence of $N N$ scattering amplitude $f(q)$. The $\tilde{\delta}(s)$-function at $r{ }_{0}^{2} / R^{2} \rightarrow 0$ must be considered as the $\delta(\mathrm{s})$-function in the integration using smoothly variable functions $\mathrm{T}_{1}, \mathrm{~T}_{2}$. So, for example

$$
\int \gamma(\mathrm{s}-\tilde{\mathrm{s}}) \mathrm{T}_{2}(\tilde{\mathrm{~s}}) \mathrm{d} \tilde{\mathrm{~s}}=\frac{\tilde{\sigma}}{2} \mathrm{~T}_{2}(\mathrm{~s})
$$

The same concerns the integration of the products of $o$ function, arguments of which are not overlapped. When integrating the products of $\delta(s)$ functions with the overlapping values of the arguments, as for example, in the simplest case

$$
\begin{aligned}
\mathrm{I}_{2} & =\int \mathrm{T}_{1}\left(\mathrm{~b}-\mathrm{s}_{1}\right) \mathrm{T}_{1}\left(\mathrm{~b}-\mathrm{s}_{2}\right) \mathrm{T}_{2}\left(\tilde{\mathrm{~s}}_{1}\right) \mathrm{T}_{2}\left(\tilde{\mathrm{~s}}_{2}\right) \tilde{\delta}_{2}\left(\mathrm{~s}_{1}-\tilde{\mathrm{s}}_{1}\right) * \\
& * \tilde{\delta}^{\left(\mathrm{s}_{1}-\tilde{\mathrm{s}}_{2}\right) \delta\left(\mathrm{s}_{2}-\tilde{\mathrm{s}}_{1}\right) \delta\left(\mathrm{s}_{2}-\tilde{\mathrm{s}}_{2}\right) \mathrm{ds} \mathrm{~s}_{1} \tilde{\mathrm{~s}}_{2} \mathrm{~d} \tilde{\mathrm{~s}}_{2} \mathrm{~d} \tilde{\mathrm{~s}}_{1}} \\
\mathrm{I}_{3} & =\int \mathrm{T}_{1}\left(\mathrm{~b}-\mathrm{s}_{1}\right) \mathrm{T}_{1}\left(\mathrm{~b}-\mathrm{s}_{2}\right) \mathrm{T}\left(\mathrm{~b}-\mathrm{s}_{3}\right) \mathrm{T}_{2}\left(\tilde{\mathrm{~s}}_{1}\right) \mathrm{T}_{2}\left(\tilde{\mathrm{~s}}_{2}\right) \mathrm{T}_{2}\left(\tilde{\mathrm{~s}}_{3}\right) \tilde{\delta}\left(\tilde{\mathrm{s}}_{1}-\tilde{\mathrm{s}}_{1}\right) * \\
& * \tilde{\delta}\left(\mathrm{~s}_{1}-\tilde{\mathrm{s}}_{2}\right) \tilde{\delta}\left(\mathrm{s}_{2}-\tilde{\mathrm{s}}_{3}\right) \tilde{\delta}\left(\mathrm{s}_{2}-\tilde{\mathrm{s}}_{2}\right) \tilde{\delta}\left(\mathrm{s}_{3}-\tilde{\mathrm{s}}_{3}\right) \tilde{\delta}_{3}\left(\mathrm{~s}_{3}-\tilde{\mathrm{s}}_{1}\right) \mathrm{ds} \mathrm{~s}_{1} \mathrm{ds}_{2} * \\
& * \mathrm{ds}_{3} \tilde{\mathrm{~s}}_{1} \mathrm{dr}_{2} \tilde{\mathrm{ds}}_{3},
\end{aligned}
$$

in order to obtain final results one must use the concrete form of the function $\Phi(X)$. It is obvious that only with the accuracy of the term of the order of $r_{0}^{2} / R R_{1,2}^{2}$

$$
\begin{align*}
& \mathrm{I}_{2}=\frac{\mathrm{N}_{2}}{\pi \mathrm{r}_{0}^{2}} \rho\left[\mathrm{r}_{1}(\mathrm{~b}-\mathrm{s}) \mathrm{T}_{2}(\mathrm{~s})\right]^{2} \mathrm{~d}^{2} \mathrm{~s} \\
& \mathrm{I}_{3}=\frac{\mathrm{N}_{3}}{\pi \mathrm{r}_{0}^{2}} \int\left[\mathrm{~T}_{1}(\mathrm{~b}-\mathrm{s}) \mathrm{T}_{2}(\mathrm{~s})\right]^{3} \mathrm{~d}^{2} \mathrm{~s} . \tag{14}
\end{align*}
$$

The exact values of the coefficients $N_{2}, N_{3}$, as well as the relation between them, depend on the form of the function $\Phi(X)$ or on the differential cross-section form for NN scattering. Using the above-mentioned properties of expressions ( 11 b ), ( 11 d ) and their structure and accounting for the dimension considerations we obtain

$$
\begin{align*}
& x_{1}(b)=\frac{2}{\tilde{\sigma}} \int \mathrm{~d}^{2} \mathrm{~s} x[\exp (-\mathrm{y})-1] \\
& \chi_{\mathrm{n}}(\mathrm{~b})=\frac{2}{\widetilde{\sigma}} \int \mathrm{~d}^{2} \mathrm{~s}[\mathrm{x} \exp (-\mathrm{y})]^{2} \phi_{\mathrm{n}}\left(\mathrm{y}, \mathrm{r}_{0}\right) \quad \mathrm{n} \geq 2 \tag{15}
\end{align*}
$$

and so on, where

$$
\begin{aligned}
& \mathrm{E}_{\mathrm{n}}\left(\mathrm{~s}_{1}, \ldots, \mathrm{~s}_{\mathrm{n}}\right)=\exp \left(\int \mathrm{d} \overrightarrow{\mathrm{~s}}_{\mathrm{Q}}(\tilde{s})\left\{\prod_{i=1}^{n}\left[1 \sim \gamma\left(\mathrm{~s}_{\mathrm{i}}-\overline{\mathrm{s}}\right)\right]-1\right\}\right) \\
& \text { Since the values } \chi_{n} \text { are formed of the combinations of }
\end{aligned}
$$ expressions of type $\Gamma_{A_{1}}^{(0)} A_{2}\left(A_{1}=\infty, A_{2}=1,2, \ldots n\right)$, the problem seems to be reduced to the initial. However, this is not so.

The structure of those combinations is such that integrands in (11b), (11d), as functions of relative variables $s_{i}-s_{\ell}, s_{i}-\tilde{s}$, substantially differ from zero only in the limits of nucleon-nucleon interaction radius $r_{0}$. It is not difficult to be convinced of it expanding the values $E_{k}\left(s_{1} \ldots, s_{k}\right)$ in series by magnitudes of type $\int \ddot{\mathrm{ds}} \mathrm{T}_{2}(\underset{\mathrm{~s}}{ }) \prod_{\mathrm{i}=1}^{\mathrm{k}} \gamma\left(\tilde{\mathrm{s}}-\mathrm{s}_{\mathrm{i}}\right) \quad \mathrm{k} \geq 2$ and considering the $\delta$-like
behaviour of the profile function $\gamma$ in comparison with smooth change of thickness functions $T_{1}$ and $T_{2}$, if $r_{0}^{2} / R^{2}\left(A_{1(2)}\right)<1 \quad(R$ is the radius of nuclei), that is practically always satisfied. Taking into account the normalization

$$
\int y(\mathrm{~s}) \mathrm{ds}=\frac{\bar{\sigma}}{2}, \quad \bar{\sigma}=\sigma_{\mathrm{NN}}^{\mathrm{tot}}\left(1-\mathrm{i} \frac{\operatorname{Ref}(\mathbf{0})}{\operatorname{Imf}(0)}\right)
$$

we write $\gamma(\mathrm{s})$ in the form

$$
y(\mathrm{~s})=\frac{\tilde{\sigma}}{2} \tilde{\delta}(\mathrm{~s})
$$

$$
\begin{equation*}
\tilde{\delta}(\mathrm{s})=-\frac{1}{\pi r_{0}^{2}} \Phi\left(\frac{\mathrm{~s}^{2}}{\mathrm{n}^{2}}\right) \quad \int_{0}^{\infty} \Phi(\mathrm{X}) \mathrm{dX}=1 \tag{12}
\end{equation*}
$$

$\Phi(\mathrm{X}) \ll 1$ at $\mathrm{X} \gg 1$.
The concrete form of $\Phi(X)$ is determined by the q-dependence of $N N$ scattering amplitude $f(q)$. The $\tilde{\delta}(\mathrm{s})$-function at $\mathrm{r}_{0}^{2} / \mathrm{R}^{2} \rightarrow 0$ must be considered as the $\delta(\mathrm{s})$-function in the integration using smoothly variable functions $\mathrm{T}_{1}, \mathrm{~T}_{2}$. So, for example

$$
\int \gamma(\mathrm{s}-\tilde{\mathrm{s}}) \mathrm{T}_{2}(\tilde{\mathrm{~s}}) \mathrm{d} \tilde{\mathrm{~s}}=\frac{\tilde{\sigma}}{2} \mathrm{~T}_{2}(\mathrm{~s})
$$

The same concerns the integration of the products of $\delta$ function, arguments of which are not overlapped. When integrating the products of $\delta(s)$ functions with the overlapping values of the arguments, as for example, in the simplest case

$$
\begin{aligned}
\mathrm{I}_{2} & =\int \mathrm{T}_{1}\left(\mathrm{~b}-\mathrm{s}_{1}\right) \mathrm{T}_{1}\left(\mathrm{~b}-\mathrm{s}_{2}\right) \mathrm{T}_{2}\left(\tilde{\mathrm{~s}}_{1}\right) \mathrm{T}_{2}\left(\tilde{\mathrm{~s}}_{2}\right) \tilde{\delta}_{2}\left(\mathrm{~s}_{1}-\tilde{\mathrm{s}}_{1}\right) * \\
& * \tilde{\delta}^{\left(\mathrm{s}_{1}-\tilde{\mathrm{s}}_{2}\right) \delta\left(\mathrm{s}_{2}-\tilde{\mathrm{s}}_{1}\right) \delta\left(\mathrm{s}_{2}-\tilde{\mathrm{s}}_{2}\right) \mathrm{ds}_{1} \mathrm{~d} \tilde{\mathrm{~s}}_{2} \mathrm{~d}_{2} \tilde{\mathrm{~s}}_{2} \tilde{\mathrm{~s}}_{1}} \\
\mathrm{I}_{3} & =\int \mathrm{T}_{1}\left(\mathrm{~b}-\mathrm{s}_{1}\right) \mathrm{T}_{1}\left(\mathrm{~b}-\mathrm{s}_{2}\right) \mathrm{T}\left(\mathrm{~b}-\mathrm{s}_{3}\right) \mathrm{T}_{2}\left(\tilde{\mathrm{~s}}_{1}\right) \mathrm{T}_{2}\left(\ddot{\mathrm{~s}}_{2}\right) \mathrm{T}_{2}\left(\tilde{\mathrm{~s}}_{3}\right) \tilde{\delta}\left(\mathrm{s}_{1}-\tilde{\mathrm{s}}_{1}\right) * \\
& * \tilde{\delta}\left(\mathrm{~s}_{1}-\tilde{\mathrm{s}}_{2}\right) \tilde{\delta}\left(\mathrm{s}_{2}-\tilde{\mathrm{s}}_{3}\right) \tilde{\delta}\left(\mathrm{s}_{2}-\tilde{\mathrm{s}}_{2}\right) \tilde{\delta}_{3}\left(\mathrm{~s}_{3}-\tilde{\mathrm{s}}_{3}\right) \tilde{\delta}_{3}\left(\mathrm{~s}_{3}-\tilde{\mathrm{s}}_{1}\right) \mathrm{ds}_{1} \mathrm{ds}_{2} * \\
& * \mathrm{ds}_{3} \tilde{\mathrm{~s}}_{1} \mathrm{ds}_{2} \tilde{\mathrm{ds}}_{3},
\end{aligned}
$$

in order to obtain final results one must use the concrete form of the function $\Phi(X)$. It is obvious that only with the accuracy of the term of the order of $r_{0}^{2} / R R_{1,2}^{2}$

$$
\begin{align*}
& \mathrm{I}_{2}=\frac{\mathrm{N}_{2}}{\pi \mathrm{r}_{0}^{2}} \int\left[\mathrm{r}_{1}(\mathrm{~b}-\mathrm{s}) \mathrm{T}_{2}(\mathrm{~s})\right]^{2} \mathrm{~d}^{2} \mathrm{~s} \\
& \mathrm{I}_{3}=\frac{\mathrm{N}_{3}}{\pi \mathrm{r}_{0}^{2}} \int\left[\mathrm{~T}_{1}(\mathrm{~b}-\mathrm{s}) \mathrm{T}_{2}(\mathrm{~s})\right]^{3} \mathrm{~d}^{2} \mathrm{~s} . \tag{14}
\end{align*}
$$

The exact values of the coefficients $\mathrm{N}_{2}, \mathrm{~N}_{3}$, as well as the relation between them, depend on the form of the function $\$(X)$ or on the differential cross-section form for NN scattering. Using the above-mentioned properties of expressions ( 11 b ), ( 11 d ) and their structure and accounting for the dimension considerations we obtain

$$
\begin{align*}
& x_{1}(b)=\frac{2}{\tilde{\sigma}} \int \mathrm{~d}^{2} \mathrm{~s} x[\exp (-\mathrm{y})-1] \\
& \chi_{\mathrm{n}}(\mathrm{~b})=\frac{2}{\tilde{\sigma}} \int \mathrm{~d}^{2} \mathrm{~s}[\mathrm{x} \exp (-\mathrm{y})]^{2} \phi_{\mathrm{n}}\left(\mathrm{y}, \mathrm{r}_{0}\right) \quad \mathrm{n} \geq 2 \tag{15}
\end{align*}
$$

where $x, y, r_{0}$ denote the dimensionless combination of the values

$$
\begin{equation*}
\mathrm{x}=\frac{\tilde{\sigma}}{2} \mathrm{~T}_{1}(\mathrm{~b}-\mathrm{s}), \quad \mathrm{y}=\frac{\tilde{\sigma}}{2} \mathrm{~T}_{2}(\mathrm{~s}), \quad \mathrm{r}_{0}=\frac{\tilde{\sigma}}{4 \pi \mathrm{r}_{0}^{2}} \tag{16}
\end{equation*}
$$

The concrete form of $\phi_{n}$ is different for various parametrization $\Phi(X)$ because of the above-discussed dependence of coefficients $N_{2}$ and $N_{3}$ on the form of $\Phi(X)$.

Taking into account that the hadron-nucleus scattering amplitude depends only on the forward nucleon-nucleon scattering amplitude $\left(y(\mathrm{~b})=\frac{\tilde{\sigma}}{2} \delta(\mathrm{~b})\right)$ at $\mathrm{r}_{0}^{2} / \mathrm{R}^{2}\left(\mathrm{~A}_{1.2}\right) \rightarrow 0$, it is improbable that the appearing in the nucleus-nucleus scattering phase dependence on the NN amplitude behaviour at the different from zero transverse momentum affects essentially the $A_{1} A_{2}$ scattering characteristics.

This means that the dominant contribution to $x_{n}$ must introduce "the model-independent" part determined by $\left.\dot{\phi}_{\mathrm{n}}\left(\mathrm{y}, \gamma_{0}\right)\right|_{\gamma_{\mathrm{o}}=0}$. We expand the function $\phi_{\mathrm{i}}$ into a series by the parameter $\gamma_{0}$

$$
\begin{equation*}
\phi_{n}\left(y, \gamma_{0}\right)=\sum_{k=0}^{\infty} \phi_{n}^{(k)}(y) \gamma_{0}^{(k)} \tag{17}
\end{equation*}
$$

and consider first of all, "model-independent" part.
It is not difficult to test that values $\phi_{n}^{(k)}(y) \quad(n \geq 2)$ are the polynomial of the degree $n+k-1$ by the variable $y$. In particular

$$
\begin{equation*}
\phi_{n}^{(0)}=\sum_{P=1}^{n-1} a_{n}^{(0)} y^{\ell} \quad n \geq 2 . \tag{18}
\end{equation*}
$$

It is easy to obtain the concrete expressions for coefficients $\mathrm{a}_{\mathrm{n}}\left(\mathrm{D}_{\mathrm{p}}\right)$ by using direct calculation. However, it is not necessary to make, since the symmetry of the task relatively to the rearrangement $A_{1} \leftrightarrow A_{2}$, the structure of expression (18) and the condition $a\left(q_{n}=0\right.$ at $\ell \geq n$ in (18) uniquely determine all coefficients a $\rho_{n}^{0}$. Indeed, according to (15), representing $\chi(b)$ in the form

$$
\begin{align*}
& x(\mathrm{~b})=\frac{2}{\vec{\sigma}} \int \mathrm{f}(\mathrm{x}, \mathrm{y}) \mathrm{d}^{2} \mathrm{~s} \\
& \mathrm{f}(\mathrm{x}, \mathrm{y})=\mathrm{x}\left(\mathrm{e}^{-\mathrm{y}}-1\right)+\sum_{\mathrm{n}=2}^{\infty} \frac{1}{\mathrm{n}!}\left(\mathrm{xe}^{-\mathrm{y}}\right)^{\mathrm{n}} \phi_{\mathrm{n}}(\mathrm{y}) \tag{19}
\end{align*}
$$

in consequence of the symmetry $\left(A_{1} \leftrightarrow A_{2}\right)$ we have

$$
\begin{equation*}
f(x, y)=f(y, x) \ldots \tag{20}
\end{equation*}
$$

We present the function $f(x, y)$ in the double series expansion:

$$
\begin{equation*}
f(x, y)=\sum_{m, n=1}^{\infty} g_{m m} x^{n} y^{m} \tag{21}
\end{equation*}
$$

where, according to (20),

$$
\begin{equation*}
g_{m n}=g_{n m}, \quad g_{m n} \because g_{m n}\left(\gamma_{0}\right) \tag{22}
\end{equation*}
$$

Then, taking into account (21) and (22) for the zeroth coefficients over $\gamma_{0}$ approximation, one obtains

$$
\begin{align*}
& \mathrm{g}_{1 \mathrm{~m}}^{\circ}=\frac{(-1)^{\mathrm{m}}}{\mathrm{~m}!} \\
& \mathrm{g}_{\mathrm{nm}}^{\circ}=\sum \mathrm{a}_{n \mathrm{n}}^{\circ} \frac{(-n)^{\mathrm{m}-l}}{(m-\eta)!} \tag{23}
\end{align*}
$$

Taking into consideration (22), we obtain successively

$$
\begin{align*}
& a_{21}^{(0)}=2 g_{21}^{\circ}=2 g_{12}^{\circ}=1 \\
& a_{32}^{\circ}=2 g_{32}^{\circ}=g_{23}^{\circ}=1 \tag{24}
\end{align*}
$$

and so on. Hence, it follows

$$
\begin{align*}
& g_{2 m}=(-1)^{m} \frac{2^{m-1} m}{m!2!} \\
& g_{3 m}=(-1)^{m+3} \frac{3^{m-1} m^{2}}{3!m!},  \tag{25}\\
& \ldots \ldots \ldots \ldots \ldots \\
& g_{n m}=(-1)^{m+n} \frac{n^{m-1} m^{n-1}}{m!n!}
\end{align*}
$$

This is the result obtained by Andreev in the framework of the generating function method which allows one to calculate the phase function $\chi(b)$ as the double series of the convolutions

$$
\frac{2}{\ddot{\sigma}} \int\left(\frac{\tilde{\sigma}}{2} \mathrm{~T}_{1}(\mathrm{~b}-\mathrm{s})\right)^{\mathrm{m}}\left(\frac{\tilde{\sigma}}{2} \mathrm{~T}_{2}(\mathrm{~s})\right)^{\mathrm{n}} \mathrm{~d}^{2} \mathrm{~s}
$$

Since the values ( $\tilde{\sigma}, 2 \mathrm{~T}_{1,2}$ ) are not small for a majority of nuclei and the coefficients $g_{m n}$ at large $m$ and $n(m-n)$ do not tend to zero, it is questionable to limit oneself to several lower terms of expansion (21) at the calculations of nucleus-nucleus scattering characteristics. Therefore, it is important to find the closed expression for the series sum.

## IV. SERIES SUMMATION

Assume that $x$ and $y$ are real values. This corresponds to the neglection of the NN scattering amplitude real part in comparison with the imaginary one. We write the values $m^{n-1}$ and $n^{1 m-1}$ formally so that

$$
\begin{equation*}
\left.m^{n-1}=\int \delta^{(n \cdot 1}(z) e^{-m z} d z, \quad n^{m+1} z \iint \delta^{(m-1}\right)(u) e^{-n u} d u \tag{26}
\end{equation*}
$$

and substitute them to the series

$$
\begin{equation*}
f^{\circ}(x, y)=\sum_{m, n}^{\infty}(-1)^{m ; n} \frac{x^{m} y^{n} m^{1!-1} n^{m-1}}{m!n!} \tag{27}
\end{equation*}
$$

Taking into account, again purely formally,

$$
\begin{align*}
& \sum_{m=1}^{\infty}\left(-x e^{-u}\right) \frac{\delta^{m}(z)}{m!}=\delta\left(z-x e^{-u}\right) \\
& \sum_{m=1}^{\infty}\left(-x e^{-u}\right) \frac{\delta^{m-1}(z)}{m!}=\int_{0}^{x} \delta\left(z-x e^{-u}\right) d x^{\prime}=  \tag{28}\\
& =\theta\left(z-x e^{-u}\right)-\theta(z) \\
& \sum_{n=1}^{\infty}-\left(-y e^{-z}\right){ }^{n} \delta^{(n-1)}(u) \\
& n!
\end{align*}
$$

Performing accurate summation over $m$ in (27), on the one hand, and expanding (30) in series by the degree, on the other hand, it is easy to infer that both expressions (27) and (30) may be presented in the form

$$
f(x, y)=\sum_{n=1}^{\infty} \frac{x^{n}}{n!} \frac{1}{n}\left(y \frac{d}{d y}-\right)^{n-1}\left(e^{-n y}-1\right)
$$

and equal each other.
So, the problem of the double series summation is reduced, essentially, to the solution of the system of equations

$$
\begin{align*}
& z=x e^{-u}  \tag{31a}\\
& u=y e^{-z} \tag{31b}
\end{align*}
$$

for two variables $u, z$ or of one equation $\ln \frac{z}{x}+y e^{-z}=0$ for the variable $z$ with the subsequent determination u through (31) which is very simply performed by computer calculations.

## V. CORRECTION OF THE ORDER OF $\gamma_{0}$

We consider now the question about the "model-dependent" component of phase function $\chi$ (b).

The direct calculation ${ }^{\prime 2}$ of the corrections of the order $\gamma$ with $k_{6} 4$ to the coefficients $g_{m n} m+n<9$ in the model with Gaussian parametrization of the NN scattering amplitude

$$
\gamma(\mathbf{b})=-\frac{\tilde{\sigma}}{4 \pi r_{0}^{2}} \exp \left(-\frac{\mathbf{b}^{2}}{2 r_{0}^{2}}\right), \quad \gamma(0)=\gamma_{0}
$$

shows that these corrections are small for the lower coefficients, but they increase with $(n+m)$. So, for example,
if $\quad \mathrm{g}_{22}^{(1)} / \mathrm{g}_{22}^{(0)}=-0.063 \gamma_{0}$,
then $\mathrm{g}_{45}^{(1)} / \mathrm{g}_{45}^{(0)}=-0.621 \gamma_{0}$,
i.e., for the larger coefficients $g_{m n}$ the corrections turn out to be comparable with the main effect. However, taking into account that in the calculation of $\chi^{(0)}(\mathrm{b})$ the contributions of the higher terms to the alternating series (27) are mutually cancelled, it is impossible to draw the definite conclusion about the quantities of the order $y_{0}$ on the basis of (32).

It is desirable to obtain the closed expression similar to (30) at least for the contribution of the order $\gamma_{0}$ to $x$ (b) and to compare them with the contribution of the zeroth approximation $\chi^{(0)}(\mathrm{b})$.

Since values $\phi_{n}^{(1)}(y)$ are the polynomials of degree $n$ (see (18), the structure of the expression for $\chi_{n}$ in (15) and condition (20) do not define unambiguously all the coefficients $a_{n}^{(1)}$, but allow one to express them through the magnitudes $b_{n}=\gamma_{0} a_{11 n}^{(1)}$. This allows one to connect the coefficients $g_{m n}^{(1)}$ with the quantities $b_{n}$

$$
\begin{aligned}
& g_{m n}^{(1)}=(-1)^{m+n} \sum_{\ell=2}^{\infty} c_{\ell} \frac{m^{n-\ell} n^{m-\ell}}{(n-\ell)!(m-\ell)!} \\
& c_{\ell}=b_{\ell}-\sum_{k=2}^{\ell-1} \frac{e^{\ell-k}}{(\ell-k)!} c_{k}, \quad c_{2}=b_{2}
\end{aligned}
$$

Employing the same formal approach of the double series summation as above it is not difficult to obtain

$$
\sum_{m, n=\ell}^{\infty}(-1)^{m+n} \frac{x^{m} y^{n} m^{n-l} n^{m-l}}{(n-\ell)!(m-\ell)!}=\frac{(u z)^{\ell}}{1-u z}
$$

and finally

$$
\begin{equation*}
f^{(1)}(x, y)=\sum g_{m n^{(1)} x^{n}} y^{m}=\sum_{\beta=2}^{\infty} d_{\ell}(u z)^{\ell}, d_{\ell}=\sum_{k=2}^{\ell} c_{k} \tag{33}
\end{equation*}
$$

The direct and somewhat cumbersome calculation is reduced to the result

$$
\mathrm{d}_{\ell}=-\frac{1}{2 \ell}-\frac{\sigma}{4 \pi^{2}} \int\left[\mathrm{f}_{\mathrm{NN}}(\mathrm{q}) / \mathrm{f}_{\mathrm{NN}}(0)\right]^{2 \ell} \mathrm{~d}^{2} \mathrm{q}
$$

from which one determines " $f(q)$-dependence" of the main correction term to the phase $\chi^{(0)(b) .}$

Fig. 1

Assuming for the estimate

$$
\begin{equation*}
f(q) / f(0)=e^{-\frac{r^{2} q^{2}}{2}} \tag{34}
\end{equation*}
$$

we obtain

$$
\begin{aligned}
& \mathrm{d}_{\ell}=\gamma_{0} / 4 \ell^{2} \\
& \mathrm{f}^{(1)}(\mathrm{x}, \mathrm{y})=-\frac{\gamma_{0}}{4}-\left[\mathrm{uz}+\frac{1}{0} \frac{\mathrm{dt}}{\mathrm{t}} \ln (1-\mathrm{uzt})\right]
\end{aligned}
$$

The results of the numerical calculations are shown in Figs. 1,2.

The values of $\chi^{(0)}(\mathrm{b}) \quad$ are given in fig. 1 and [ $\left.\chi^{(1)}(\mathrm{b}) / \chi^{(0)}(\mathrm{b})\right] \cdot 100$ is plotted in fig. 2. It is obvious that the value $\chi^{(1)}(\mathrm{b})$ indeed is the correction to $\chi^{(b)}$ and this correction is so small that its consideration could exceed the precision, due to infiniteness in the initial magnitudes, in particular, in the nuclear density parameters. Thus, we would not consider the correction of the higher order of $\gamma_{0}$.

The authors are grateful to Prof. L.I.Lapidus and I.V.Andreev for useful discussions and interest to the present work.
