OPTIMIZED LAMBDA-PARAMETRIZATION FOR THE QCD RUNNING COUPLING CONSTANT
IN SPACELIKE AND TIMELIKE REGIONS

Submitted to "Physics Letters B".

## 1. INTRODUCTION

Perturbative QCD is intensively applied now to various processes involving large momentum transfers, both in spacelike ( $\mathrm{q}^{2}=-\mathrm{Q}^{2}<0$ ) and timelike ( $\mathrm{q}^{2}>0$ ) regions (for a review see $\left.{ }^{/ 1-3 /}\right)$. However, the coupling constant $g(\mu)$ (i.e., the expansion parameter) is defined usually with the reference to some Euclidean (spacelike) configuration of momenta of scale $\mu$. For spacelike $q$ this produces no special complications. One simply uses the renormalization group to sum up the logarithmic corrections $\left(g^{2}(\mu) \ln \left(Q^{2} / \mu^{2}\right)\right)^{N}$ that appear in higher orders and arrives at the expansion in the effective coupling constant $a_{s}\left(Q^{2}\right)$ which in the lowest approximation is given by the famous asymptotic freedom formula ${ }^{1 / 1}$.

$$
\begin{equation*}
a_{\mathrm{s}}\left(\mathrm{Q}^{2}\right)=\frac{4 \pi}{\left(11-2 \mathrm{~N}_{\mathrm{f}} / 3\right) \ln \left(\mathrm{Q}^{2} / \Lambda^{2}\right)}, \tag{1}
\end{equation*}
$$

where $\Lambda$ is the "fundamental" scale of $Q C D$. In general, the $\Lambda$-parametrization of $\alpha_{s}\left(Q^{2}\right)$ is a series expansion in $1 / L$ (where $\left.\mathrm{L}=\ln \left(Q^{2} / \Lambda_{2}^{2}\right)\right)$, and the definition of $\Lambda$, is fixed only if the $\mathrm{O}\left(1 / \mathrm{L}^{2}\right)$-term is added to eq. ( 1$)^{/ 4 /}$.

For timelike $q$ there appear, however, $i \pi$-factors $\left(\ln \left(Q^{2} / \mu^{2}\right) \rightarrow \ln \left(\mathrm{q}^{2} / \mu^{2}\right) \pm \mathrm{i} \pi\right), \quad$ and it is not clear a priori what is the effective expansion parameter in this region. This problem has been discussed recently in a very suggestive paper by Pennington and Ross ${ }^{\prime 5}$. These authors analysed the ratio $\mathrm{R}\left(\mathrm{q}^{2}\right)=\sigma\left(\mathrm{e}^{+} \mathrm{e}^{-} \rightarrow\right.$ hadrons $) / \sigma\left(\mathrm{e}^{+} \mathrm{e}^{-} \rightarrow \mu^{+} \mu^{-}\right)$for which the analytic continuation from the spacelike to timelike region is well-defined and investigated which of the three ansätze $\left(a_{g}\left(q^{2}\right),\left|a_{g}\left(-q^{2}\right)\right| \quad\right.$ and $\operatorname{Re} a_{g}\left(-q^{2}\right)$ better absorbs the $\left(\pi^{2} / L^{2}\right)^{N}$-corrections * in the timelike region $q^{2}>0$. Their conclusion was that $\left|a_{\mathrm{s}}\left(-\mathrm{q}^{2}\right)\right|$ is better than $a_{\mathrm{g}}\left(\mathrm{q}^{2}\right)$ and $\operatorname{Re} \alpha_{\mathrm{s}}\left(-\mathrm{q}^{2}\right)$. Nevertheless, it is easy to demonstrate by a straightforward calculation that $\left|a_{s}\left(-q^{2}\right)\right|$ cannot absorb all the $\left(\pi^{2} / L^{2}\right)^{N}$-terms associated with the analytic continuation of the $\ln \left(\mathbf{Q}^{2} / \mu^{2}\right)$-factors. Our main goal in the present letter is to show that by using the $\Lambda$-parametrization for

[^0]
$a_{\mathrm{s}}\left(\mathrm{Q}^{2}\right)$ in the spacelike region it is possible to construct for $R\left(q^{2}\right)$ in the timelike region the expansion in which all the $\left(\pi^{2} / L^{2}\right)^{N}$ terms are summed up explicitly.

## 2. $\Lambda$-PARAMETRIZATION IN SPACELIKE REGION

The starting point for the $\Lambda$-parametrization is the Gell-Mann-Low equation taken as a series expansion in $G=a_{s} / 4 \pi$ :

$$
\begin{equation*}
\mathrm{L} \equiv \ln \left(\mathrm{Q}^{2} / \Lambda^{2}\right)=\frac{1}{\mathrm{~b}_{0} \mathrm{G}}+\frac{\mathrm{b}_{1}}{\mathrm{~b}_{0}^{2}} \ln \mathrm{G}+\Delta+\frac{\mathrm{b}_{2} \mathrm{~b}_{0}-\mathrm{b}_{1}^{2}}{\mathrm{~b}_{0}^{3}} \mathrm{G}+\mathrm{O}\left(\mathrm{G}^{2}\right) \tag{2}
\end{equation*}
$$

where $\mathrm{b}_{\mathrm{k}}$ are $\beta$-function coefficients: $\mathrm{b}_{0}=11-2 \mathrm{~N}_{\mathrm{g}} / 3^{/ 1 /} \mathrm{b}_{1} \mathrm{~b}_{1}=$ $=102-38 \mathrm{~N}_{\mathrm{f}} / 3^{/ 6}, \quad \mathrm{~b}_{2}^{\text {MS }}=2857 / 2-5033 \mathrm{~N}_{\mathrm{f}} / 18+325 \mathrm{~N}_{\mathrm{f}}^{2} / 54^{\prime / 7 /}$. The parameter $\Delta$ in eq. (2) is due to the lower boundary of the GML integra1 ${ }^{18,9 /}$. By a particular choice of $\Delta$ one fixes the definition of $\Lambda: \Lambda=\Lambda(\Delta)$. . Eq. (2) is solved by iterations and the result is reexpanded in $1 / L$

$$
\begin{equation*}
a_{s}\left(Q^{2}\right)=\frac{4 \pi}{b_{0} \mathrm{~L}}\left\{1-\frac{L_{1}}{\mathrm{~L}}+\frac{1}{\mathrm{~L}^{2}}\left[\mathrm{~L}_{1}^{2}-\frac{\mathrm{b}_{1}}{\mathrm{~b}_{0}^{2}} \mathrm{~L}_{1}+\frac{\mathrm{b}_{2} \mathrm{~b}_{0}-\mathrm{b}_{1}^{2}}{\mathrm{~b}_{0}^{4}}\right]+\mathrm{O}\left(1 / \mathrm{L}^{3}\right)\right\}, \tag{3}
\end{equation*}
$$

where

$$
\begin{equation*}
\mathrm{L}_{1}=\frac{\mathrm{b}_{1}}{\mathrm{~b}_{0}^{2}} \ln \left(\mathrm{~b}_{0} \mathrm{~L}\right)-\Delta \tag{4}
\end{equation*}
$$

The expansion (3) is useful, of course, only if it converges rapidly enough. In fact, the convergence of the $1 / \mathrm{L}$ series depends (i) on the value of $L$ we are interested in and (ii) on the choice of $\Delta$.

We emphasize that the most important for perturbative QCD is the region $L>3$, since $L=3$ corresponds to $a_{s}-0.5$, and the reliability of perturbation theory for larger $a_{\mathrm{s}}$ is questionable. Hence, in a realistic situation the naive expansion parameter $1 / \mathrm{L}$ is smaller than (but usually close to) one third Of course, $1 / 3$ is not very small, so one must check the coefficients of the $1 / \mathrm{L}$ expansion more carefully. First, there is a $\Delta$-convention-independent term ( $\left.\mathrm{b}_{2} \mathrm{~b}_{0}-\mathrm{b}_{1}^{2}\right) /\left(\mathrm{b}_{0}^{4} \mathrm{~L}^{2}\right)$ which reduces for $N_{f}=3$ to roughly $0.25 / L^{2}$ and gives, therefore, less than $3 \%$-correction to the simplest formula (1).
 and one should choose $\Delta$ so as to minimize the upper value of the ratio $L_{1} / L$ in the $L$-region of interest.

[^1]If one takes, e.g., $\Delta=\Delta_{\mathrm{gpt}}=\left(\mathrm{b}_{1} / \mathrm{b}_{0}^{2}\right) \ln \left(4 \mathrm{~b}_{0}\right)$, then $L_{1}=\left(b_{1} / b_{0}^{2}\right) \ln (\mathrm{L} / 4) \quad$ and the ratio $L_{1} / \mathrm{L}$ is smaller than $7 \%$ in the whole region $L>3$. Another choice ${ }^{10 /}$ is to take $\Delta=\Delta\left(Q_{0}^{2}\right)=\left(\mathrm{b}_{1} / \mathrm{b}_{0}^{2}\right) \ln \left(\mathrm{b}_{0} \mathrm{~L}_{0}\right)$, where $\mathrm{L}_{0}=\ln \left(\mathrm{Q}_{0}^{2} / \Lambda^{2}\right)$ and $Q_{0}^{2}$ lies somewhere in the middle of the $Q^{2}$-region analysed. In this case $L_{1}=\left(b_{1} / b_{0}^{2}\right) \ln \left(L / L_{0}\right)$, i.e., $L_{1} / L$ is zero for $Q^{2}=Q_{0}^{2}$ and smaller than $7 \%$ for all $Q^{2}$ in the region where $\mathrm{L}>3$. An important observation is that both the choices minimize the corrections not only in eq. (3) but also in the GML equation (2).

Really, for small $G$ the only dangerous term in eq. (2) is $\ln G$, hence, the best thing to do is to compensate it by taking $\Delta=-\left(\mathrm{b}_{1} / \mathrm{b}_{0}^{2}\right) \ln \overline{\mathrm{G}}$, where $\overline{\mathrm{G}}$ is $a_{\mathrm{s}}\left(\mathrm{Q}^{2}\right) / 4 \pi \quad$ averaged (in some sense) over the relevant $Q^{2}$-region. After this has been done, one may safely solve eq. (2) by iterations and perform the $1 / \mathrm{L}$-expansion. For a proper choice of $\Delta$ eq. (3) has $1 \%$ accuracy for $\mathrm{L}>3$, and, moreover, the total correction to the simplest formula (1) is less than $10 \%$. However, accepting the most popular prescription $\Delta_{\text {pop }}=\left(\mathrm{b}_{1} / \mathrm{b}_{0}^{2}\right) \ln \mathrm{b}_{0}=\Delta\left(\mathrm{Q}^{2}=\mathrm{e} \Lambda^{2}\right)$
(the only motivation for $\Delta_{\text {pop }}$ being the "aesthetic" criterion that $L_{1}$ should have the shortest form $L_{1}=\left(b_{1} / b_{0}^{2}\right) \ln L$ ) ) one minimizes $L_{1} / L$ in the region $Q^{2} \sim 3 \Lambda^{2}$ nobody is really interested in. Moreover, in the important region L -3 one has $L_{1}^{\text {pop }} / \mathrm{L} \sim 1 / 3$ and the convergence of the $1 / \mathrm{L}$-series is very poor in this case.

Thus, the $\Lambda$-parametrization (eq. (3)) gives a rather compact and sufficiently precise expression for the effective coupling constant in the spacelike region provided a proper choice of the $\Delta$-parameter has been made.

## 3. $\Lambda$-PARAMETRIZATION AND $R\left(e^{+} e^{-} \rightarrow\right.$ HADRONS; s)

The standard procedure(see,e.g., $/ 11 /$ and references therein) is to calculate the derivative $D\left(Q^{2}\right)=Q^{2} d / d Q^{2}$ of the vacuum polarization $t\left(Q^{2}\right)$ related to $R$ by

$$
\begin{equation*}
R(s)=\frac{1}{2 \pi i}(t(-s+i \epsilon)-t(-s-i \epsilon)) \tag{5}
\end{equation*}
$$

In perturbative $Q C D D\left(Q^{2}\right)$ is given by the $a_{s}\left(Q^{2}\right)$-expansion:

$$
\begin{equation*}
\mathrm{D}\left(\mathrm{Q}^{2}\right)=\sum_{\mathrm{q}} \mathrm{e}_{\mathrm{q}}^{2}\left\{1+\frac{a_{\mathrm{s}}\left(\mathrm{Q}^{2}\right)}{\pi}+\mathrm{d}_{2}\left(\frac{\alpha_{\mathrm{s}}\left(Q^{2}\right)}{\pi}\right)^{2}+\mathrm{d}_{3}\left(\frac{a_{\mathrm{s}}\left(\mathrm{Q}^{2}\right)}{\pi}\right)^{2}+\ldots\right\} \tag{6}
\end{equation*}
$$

Only $d_{2}$ is known now 11,12 , its value depending on the renormalization scheme chosen. Using eq. (5) and the definition of $D$, one can relate $R(s)$ (or, more precisely, its perturbative QCD version $R^{Q C D}(s)$ ) directly to $D\left(Q^{2}\right)$

$$
\begin{equation*}
\mathrm{R}^{\mathrm{QCD}}(\mathrm{~s})=\frac{1}{2 \pi \mathrm{i}} \int_{-\mathrm{s}-\mathrm{i} \epsilon}^{-\mathrm{s}+\mathrm{i} \epsilon} \mathrm{D}(\sigma) \frac{\mathrm{d} \sigma}{\sigma} . \tag{7}
\end{equation*}
$$

Integration in eq. (7) goes below the real axis from $-\mathrm{s}-\mathrm{i}$ to zero and then above the real axis to $-s+i \epsilon$.

In a shorthand notation $D \Rightarrow R \equiv \Phi[D]$. In some important cases the integral (7) can be calculated explicitly:

$$
\begin{equation*}
1 \Rightarrow 1 \tag{8}
\end{equation*}
$$

$\frac{1}{\mathrm{~L}_{\sigma}} \Rightarrow \frac{1}{\pi} \operatorname{arctg}\left(\pi / \mathrm{L}_{\mathrm{s}}\right)=\frac{1}{\mathrm{~L}_{\mathrm{s}}}\left\{1-\frac{1}{3} \frac{\pi^{2}}{\mathrm{~L}_{\mathrm{s}}^{2}}+\ldots\right\}$,

$$
\begin{equation*}
\frac{\ln \left(\mathrm{L}_{\sigma} / \mathrm{L}_{0}\right)}{\mathrm{L}_{\sigma}^{2}} \Rightarrow \frac{\ln \left(\sqrt{\mathrm{~L}_{\mathrm{s}}^{2}+\pi^{2} / \mathrm{L}_{0}}\right)-\left(\mathrm{L}_{\mathrm{s}} / \pi\right) \operatorname{arctg}\left(\pi / \mathrm{L}_{\mathrm{s}}\right)+1}{\mathrm{~L}_{\mathrm{s}}^{2}+\pi^{2}}= \tag{9}
\end{equation*}
$$

$$
\begin{equation*}
=\frac{\ln \left(\mathrm{L}_{\mathrm{s}} / \mathrm{L}_{0}\right)}{\mathrm{L}_{\mathrm{s}}^{2}}\left\{1-\frac{\pi^{2}}{\mathrm{~L}_{\mathrm{s}}^{2}}+\ldots\right\}+\frac{5}{6} \frac{\pi^{2}}{\mathrm{~L}_{\mathrm{s}}^{4}}+\ldots . \tag{11}
\end{equation*}
$$

$$
\frac{1}{\mathrm{~L}_{\sigma}^{2}} \Rightarrow \frac{1}{\mathrm{~L}_{\mathrm{s}}^{2}+\pi^{2}}=\frac{1}{\mathrm{~L}_{\mathrm{s}}^{2}}\left\{1-\frac{\pi^{2}}{\mathrm{~L}_{\mathrm{s}}^{2}}+\cdots\right\}
$$

$$
\begin{equation*}
\frac{1}{L_{\sigma}^{n}} \Rightarrow(-1)^{n} \frac{1}{(n-1)!}\left(-\frac{d}{d L_{s}}\right)^{n-2} \frac{1}{L_{s^{+}}^{2}-\pi^{2}}=\frac{1}{L_{s}^{n}}\left\{1-\frac{\pi^{2}}{L_{s}^{2}} \frac{n(n+1)}{6}+\ldots\right\}, \tag{12}
\end{equation*}
$$

where $\mathrm{L}_{\mathrm{s}}=\ln \left(\mathrm{s} / \Lambda^{2}\right), \mathrm{L}_{\sigma}=\ln \left(\sigma / \Lambda^{2}\right)$ and $\mathrm{L}_{0}$ is the constant depending on the $\Delta$-choice.

Using the $\Lambda$-parametrization for $a_{s}(\sigma)$ and incorporating eqs. (8)-(12) (as well as their generalizations for $\ln ^{2} \mathrm{~L} / \mathrm{L}^{3}$, $\ln L / L^{3}$ etc.) produces the expansion for $R^{Q C D}(s)$

$$
\begin{equation*}
R^{Q C D}(s)=\left(\sum_{q} e_{q}^{2}\right)\left\{1+\sum_{k=1} d_{k} \Phi\left[\left(a_{s} / \pi\right)^{k}\right]\right\} \tag{13}
\end{equation*}
$$

in which all the $\left(\pi^{2} / L^{2}\right)^{N}$-terms are summed up explicitly.

## 4. QUEST FOR THE BEST EXPANSION PARAMETER

Note that the expansion (13) is not an expansion in powers of some particular parameter since the application of the $\Phi$-operation normally violates nonlinear relations: $\Phi\left[1 / L^{2}\right] \neq$ $\neq(\Phi[1 / L])^{2}$, etc. A priori, there are no grounds to believe that a power expansion is better than any other (say, Fourier). In fact, the expansion (13) converges better than the genera-
ting expansion (6) for $D(\sigma)$ because, as it follows from eqs. (9)-(12), $\Phi\left[\alpha_{\mathbf{s}}^{\mathrm{N}}\right]$ is always smaller than $a_{\mathrm{s}}^{\mathrm{N}}$. Moreover,
$\left(\Phi\left[a_{s}^{N+1}\right]^{1 / N+1}<\left(\Phi\left[a_{\mathrm{s}}^{\mathrm{N}}\right]\right)^{1 / \mathrm{N}}\right.$ i.e., the effective expansion parameter decreases in higher orders. Thus, if one succeeded in obtaining a good $a_{\mathrm{s}}^{\mathrm{N}}$ expansion for $\mathrm{D}_{\mathrm{N}}(\sigma)$ (with all $d_{N}$ being small numbers), then the resulting $\Phi\left[\alpha_{\mathrm{s}}^{\mathrm{N}}\right]$-expansion for $R^{Q C D}(s)$ is even better, and the best thing to do is to leave it as it is.

However, if one insists that the result for $R^{Q C D}$ (s) should have a form of a power expansion, then the best expansion parameter is evidently $\Phi\left[\alpha_{\mathrm{s}} / \pi\right]$ because the largest nontrivial (i.e., $O\left(\alpha_{s} / \pi\right)$ ) term of the expansion is reproduced in the exact form and only higher terms are spoiled. The analogue of the simplest $\Lambda$-parametrization for $a_{s}\left(Q^{2}\right)$ (eq. (1)) is then

$$
\begin{equation*}
\tilde{\alpha}_{s}\left(q^{2}\right)=\frac{4}{b_{0}} \operatorname{arctg}\left(\frac{\pi}{\ln \left(q^{2} / \Lambda^{2}\right)}\right) \tag{14}
\end{equation*}
$$

Using eqs. (8)-(13) it is easy to realize that $a_{s}\left(q^{2}\right)$ is really a bad expansion parameter, because if one reexpands $\tilde{\tilde{a}}_{\mathrm{s}}\left(\mathrm{q}^{2}\right)$ in $\alpha_{s}\left(q^{2}\right)$,then there appear terms with large coefficients

$$
\ddot{a}_{\mathrm{s}}\left(\mathrm{q}^{2}\right)=a_{\mathrm{s}}\left(\mathrm{q}^{2}\right)\left\{1-\frac{1}{3}\left(\frac{\pi \mathrm{~b}_{0}}{4}\right)^{2}\left(\frac{a_{\mathrm{s}}\left(\mathrm{q}^{2}\right)}{\pi}\right)^{2}+\ldots\right\} \simeq a_{\mathrm{s}}\left\{1-17\left(\frac{a_{\mathrm{s}}}{\pi}\right)^{2}+\ldots\right\} .(15)
$$

If one reexpands $\vec{a}_{\mathrm{s}}\left(\mathrm{q}^{2}\right)$ in $\operatorname{Re} a_{\mathrm{s}}\left(-\mathrm{q}^{2}\right)$ then the corresponding coefficient is even 2 times larger, whereas if $\tilde{a}_{s}\left(q^{2}\right)$ is reexpanded in $\left|\alpha_{s}\left(-q^{2}\right)\right|$, the coefficient is 2 times smaller. This observation is in full agreement with the result of ref. ${ }^{5}$ quoted in the introduction.

## 5. CONCLUDING REMARKS

It should be noted that the change of the expansion parameter as given by eq. (15) affects only the $\left(\alpha_{\mathrm{s}} / \pi\right)^{3}$ coefficient of the RQCD-expansion which has not been calculated yet. So, within the present-day accuracy, all expansions for $R^{\text {QCD }}$ have the same coefficients. It is worth emphasizing, nevertheless, that the $\pi^{2} / L^{2}$ terms produce for $\alpha_{s} \geq 0.3$ more than $20 \%$ correc tion to $a_{s}$, i.e., they are more important (for an optimal choice of the $\Delta$-parameter) than the 2 -loop corrections in eq. (3)).

To conclude, we have described the construction of an optimized (i.e., rapidly convergent) $\Lambda$-parametrization for the effective QCD coupling constant in the spacelike region, and then we used it to obtain the fastest convergent expansion for the time-like quantity $\mathrm{R}^{\mathrm{QCD}}(\mathrm{s})$. The technique outlined in the present paper can be applied also to other $R^{Q C D}-1$ ike
quantities. Such quantities do appear, e.g., in the QCD sum rule approach ${ }^{/ 13 /}$ in which the analysis of hadronic properties is based on the study of vacuum correlators of various currents. They appear also in an alternative approach ${ }^{14 /}$ based on the finite-energy sum rules $/ 15^{\prime}$. It should be stressed that
 basic integral relation, and the analysis is most conveniently performed if one has a simple analytic expression similar to that described above.

## ACKNOWLEDGEMENTS

I am grateful to A.V.Efremov and D.V.Shirkov for their interest in this work and support. I thank D.I.Kazakov, O.V.Tarasov and A.A.Vladimirov for useful discussions.
