О статистической механике систем с существенно сингулярными парными потенциалами (теоремы сходимости)

Рассматривается статистическая механика для систем с существенно сингулярными парными потенциалами. Обсуждается случай частиц с "точечными" парными сердцевинами (потенциалы типа Леннарда-Джонса). Дано строгое математическое обоснование для использования этой физической идеализации с помощью теорем о сходимости при снятии обрезания.

Работа выполнена в Лаборатории теоретической физики ОИЯИ.

On Statistical Mechanics of Systems with  
Highly Singular Two-Body Potentials

A natural cut-off procedure for two-body highly singular potentials, discussed in the previous paper (part I), is proposed. The main result is the proof of a convergence theorem for partition sum (or the free energies) when the cut-off parameter is removed to infinity. The question of stability of the cut-off interactions is also discussed. These results are illustrated by a consideration of the Lennard-Jones potential (12-6).

The investigation has been performed at the Laboratory of Theoretical Physics, JINR.

Communication of the Joint Institute for Nuclear Research

Dubna 1976

## 1. INTRODUCTION. CONVERGENCE OF CUT-OFF HAMILTONIANS

As was pointed out in ref.<sup>/1/</sup> (part I), the highly singular two-body potentials are an idealization. So, a cut-off procedure is very natural when we start to consider the physical problems connected with highly singular interactions. Therefore, the Hamiltonian  $H_L(\Lambda^N)$  generated

by the cut-off interaction  $U_N^L(x_1, \dots, x_N) = \frac{1}{2} \sum_{i \neq j}^N \Phi_L(x_i - x_j)$  in

some sense is close to the original Hamiltonian  $H(\Lambda^N)$  defined in the previous work<sup>/1/</sup>. Before formulating the corresponding results we need some preliminaries.

From the definition of the cut-off interactions:

$$\Phi_L(x) = \begin{cases} \Phi(x) & \{x: \Phi(x) \leq L\} \\ L & \{x: \Phi(x) > L\} \end{cases} \quad (1.1.)$$

it is clear that  $\{U_N^L(x_1, \dots, x_N)\}$  is a monotone sequence of functions  $U_N^L(x_1, \dots, x_N) \in L^\infty(\Lambda^N)$  such that at each point of  $\Lambda^N \setminus S_N$  it converges to  $U_N(x_1, \dots, x_N)$

$$\lim_{L \rightarrow \infty} U_N^L(x_1, \dots, x_N) = U_N(x_1, \dots, x_N) \quad \text{for } (x_1, \dots, x_N) \in \Lambda^N \setminus S_N.$$

According to the construction of  $\{U_N^L(x_1, \dots, x_N)\}$  it is evident that for  $\text{Supp}[U_N(x_1, \dots, x_N) - U_N^L(x_1, \dots, x_N)] = S_N + \Sigma_L$

$$\lim_{L \rightarrow \infty} \text{mes}(S_N + \Sigma_L) = 0. \quad (1.2)$$

Now let us consider the sequence  $\{U_N^L\}$  as operators in the Hilbert space of states  $\mathcal{H}(\Lambda^N) = L^2(\Lambda^N)$ .

**Lemma 1.1.** Let the cut-off parameters  $\{L\}$  form a nondecreasing family, then the functions  $\{U_N^L(x_1, \dots, x_N)\}$  form in the Hilbert space  $\mathcal{H}(\Lambda^N)$  a monotonic nondecreasing sequence of bounded self-adjoint operators, i.e., for  $\forall L < \infty$   $U_N^L \in \mathcal{B}(\mathcal{H})$  and for  $L \leq L'$   $U_N^L \leq U_N^{L'}$  in the sense of quadratic forms.

**Proof.** The Lemma is a straightforward consequence of definition (1.1).

**Lemma 1.2.** Let the operators  $H_L(\Lambda^N)$  be defined for each cut-off parameter  $L$  as the algebraic sum  $H_L(\Lambda^N) = H_0(\Lambda^N) + U_N^L$  then these operators are self-adjoint and  $D(H_L) = D(H_0)$ .

**Proof.** The Lemma is an immediate consequence of the well-known Kato-Rellich Theorem (see Kato <sup>/2/</sup> V, § 4). From Lemma 1.1 the operators  $U_N^L \in \mathcal{B}(\mathcal{H})$  and are self-adjoint, hence,  $D(U_N^L) \supset D(H_0)$ , so operators  $U_N^L$  are Kato-small perturbations to the self-adjoint kinetic-energy operator  $H_0(\Lambda^N)$ .

**Corollary 1.1.** For nondecreasing family of cut-off parameters  $\{L\}$  the self-adjoint operators  $\{H_L(\Lambda^N)\}$  form, in the sense of quadratic form, a monotonic nondecreasing sequence, bounded from above by the Hamiltonian  $H(\Lambda^N) = (H_0(\Lambda^N) + U_N)_{F^{1/2}}$

$$H_{L_1} \leq H_{L_2} \leq \dots \leq H, \quad (L_1 \leq L_2 \leq \dots). \quad (1.3.)$$

**Remark 1.1.** The densely defined, closed symmetric quadratic forms  $\tilde{u}_L[\psi]$  associated with bounded self-adjoint operators  $U_N^L$  are obviously bounded for  $\forall L$ . Hence they are also  $\tilde{h}_0$ -bounded, so for  $\forall L$ :

$$\tilde{h}_L = (h_0 + u_L)^\sim = \tilde{h}_0 + \tilde{u}_L. \quad (1.4)$$

**Proposition 1.1.** (Kato <sup>/2/</sup> VIII, §3). Let  $\{h_n\}$  be a nondecreasing sequence of densely defined, closed symmetric quadratic forms bounded from below by a constant  $\gamma$  and dominated from above by a similar form  $\tilde{h}$ :

$$\gamma \leq \tilde{h}_1 \leq \tilde{h}_2 \leq \dots \leq \tilde{h},$$

and let  $H_n$  be the self-adjoint operators associated with  $\tilde{h}_n$ . Then: (i) the sequence of semibounded from below self-adjoint operators  $\{H_n\}$  converges strongly in the generalized sense to a self-adjoint operator  $H'$  which is also bounded from below:

$$\text{g.s.s. - } \lim_{n \rightarrow \infty} H_n = H',$$

(ii) if  $\tilde{h}'[\psi] = (\psi, H'\psi)^\sim$  is the associated symmetric form, we have

$$\tilde{h}_n \leq \tilde{h}' \leq \tilde{h} \quad \text{for } \forall n = 1, 2, \dots,$$

(iii) for  $\forall \psi \in Q(\tilde{h}')$  the form  $\tilde{h}'[\psi]$  is the limit of  $\{\tilde{h}_n\}$ , i.e.,

$$\lim_{n \rightarrow \infty} \tilde{h}_n[\psi] = \tilde{h}'[\psi] \quad \text{for } \psi \in Q(\tilde{h}').$$

This completes the preliminaries. Now we can prove the main results of this section. We start with

**Remark 1.2.** From Proposition 1.1 and Corollary 1.1

it follows that the cut-off Hamiltonians  $H_L(\Lambda^N)$  for  $L \rightarrow \infty$  converge in the generalized strong sense to self-adjoint operator  $H'$  with the properties (i)-(iii), where  $h[\psi] = (\psi, (H_0 + U_N)\psi) \sim$ .

Now we can prove that under the conditions of Theorem 2.1<sup>/1/</sup> the Hamiltonians  $H'(\Lambda^N) = \text{g.s.s.} - \lim_{L \rightarrow \infty} H_L(\Lambda^N)$  and  $H(\Lambda^N)$  are equal one to another.

**Remark 1.3.** (Kato<sup>/2/</sup>, VIII § 4). From the monotonicity of the sequence  $\{\tilde{h}_L[\psi]\}$  (1.4) (or  $H_L(\Lambda^N)$  (1.3)) and  $\tilde{h}_L[\psi] \leq \tilde{h}[\psi]$  it follows that  $\lim_{L \rightarrow \infty} \tilde{h}_L[\psi]$  exists at least for  $\forall \psi \in Q(\tilde{h}_0)$ . Let us define a form

$$h'[\psi] = \lim_{L \rightarrow \infty} \tilde{h}_L[\psi], \quad \psi \in Q(\tilde{h}'') \quad (1.5)$$

with  $Q(\tilde{h}'')$  consisting of all  $\psi \in \bigcap_L Q(\tilde{h}_L)$  such that limit (1.5) exists. Point (iii) of Proposition 1.1. shows that  $h'[\psi]$  is a particular case of the general limiting definition (1.5), so  $h'[\psi] \leq \tilde{h}[\psi]$ . If we take into account Remark 1.1, then the limiting form  $h''[\psi]$  (1.5) can be represented also (see (1.4)) as

$$h'[\psi] = \tilde{h}_0[\psi] + \lim_{L \rightarrow \infty} (\psi, U_N^L \psi) \quad (1.6)$$

for each  $\psi \in Q(\tilde{h}_0)$  such that the limit in the right-hand side of (1.6) exists.

**Corollary 1.2.** As follows from definition (1.1) and Lemma 1.1, the operators  $\{U_N^L\}$  and the associated sequence of quadratic forms  $\tilde{u}_L[\psi] = (\psi, U_N^L \psi) \sim$  satisfy the conditions of Propositions 1.1. So,  $\text{g.s.s.} - \lim_{L \rightarrow \infty} U_N^L = U'$

and  $\lim_{L \rightarrow \infty} \tilde{u}_L[\psi] = \tilde{u}'[\psi]$  for  $\psi \in Q(\tilde{u}')$ . But in this case

it is easy to show that  $U' = U(\Lambda^N)$ .

**Lemma 1.3.** Let the cut-off parameter  $L$  tends to infinity, then the nondecreasing sequence of bounded self-adjoint operators  $\{U_N^L\}$  (1.1) converges in generalized strong sense to the closure of the singular interaction operator  $\bar{U}_N = U(\Lambda^N)$ .

**Proof.** As was pointed out, the operator of the  $N$ -particle singular interaction  $U_N(x_1, \dots, x_N)$ ,  $D(U_N) = C_0(\Lambda^N \setminus S_N)$  (see<sup>/1/</sup>) is essentially self-adjoint, i.e., it has only one self-adjoint extension which coincides with its closure so

$$D(U_N) = \text{Core } U(\Lambda^N) \quad \text{i.e., } (U(\Lambda^N) \upharpoonright D(U_N)) \sim U(\Lambda^N). \quad (1.7)$$

Hence  $U(\Lambda^N) \upharpoonright D(U_N) = U_N$  and for  $\forall \psi \in D(U_N)$

$$\begin{aligned} \int_{\Lambda^N} dx_1 \dots dx_N [U(\Lambda^N) - U_N^L]^2 |\psi|^2 &= \\ &= \int_{\Lambda^N} dx_1 \dots dx_N (U_N - U_N^L)^2 |\psi|^2 \leq \\ &\leq 2 \int_{S_N + \Sigma_L} dx_1 \dots dx_N [U_N^2 + (U_N^L)^2] |\psi|^2, \end{aligned} \quad (1.8)$$

where  $S_N + \Sigma_L = \text{Supp } (U_N - U_N^L)$ , so the right-hand side of (1.8) for  $L \rightarrow \infty$  tends to zero, because  $\lim_{L \rightarrow \infty} \text{mes}(S_N + \Sigma_L) = 0$  (1.2). Therefore for  $\forall \psi \in D(U_N) = \text{Core } U(\Lambda^N)$   $L \rightarrow \infty$

$$\lim_{L \rightarrow \infty} U_N^L \psi = U \psi. \quad (1.9)$$

But if the sequence of self-adjoint operators  $\{U_N^L\}$  converges for  $L \rightarrow \infty$  on the dense in the space  $\mathcal{H}(\Lambda^N)$  set  $D(U_N)$  to the self-adjoint operator  $U(\Lambda^N)$  and if  $D(U_N)$  is a core of  $U(\Lambda^N)$ , then, as is well-known,  $\{U_N^L\}$  conver-

ges to the operator  $U(\Lambda^N)$  strongly in the generalized sense (see, e.g., Kato<sup>/2/</sup>, VIII, § 1):

$$\text{g.s.s. - } \lim_{L \rightarrow \infty} U_N^L = U(\Lambda^N). \quad (1.10)$$

**Corollary 1.3.** The sequence  $\tilde{u}_L[\psi] = (\psi, U_N^L \psi)$  for  $L \rightarrow \infty$  and  $\psi \in Q(\tilde{u})$  converges to the form  $\tilde{u}[\psi] = (\psi, U\psi)$ , so the form  $\tilde{u}[\psi] = \tilde{u}[\psi]$  (see Corollary 1.2). Therefore for  $\forall \psi \in Q(\tilde{h}_0) \cap Q(\tilde{u})$  (see (1.6)):

$$h'[\psi] = \tilde{h}_0[\psi] + \lim_{L \rightarrow \infty} (\psi, U_N^L \psi) = \tilde{h}_0[\psi] + \tilde{u}[\psi]. \quad (1.11)$$

From (1.11), Remarks 1.2, 1.3 and point (ii) of Proposition 1.1., it follows that

$$\tilde{h}_0[\psi] + \tilde{u}[\psi] \geq h'[\psi] \leq \tilde{h}[\psi] = (\tilde{h}_0 + \tilde{u})[\psi]. \quad (1.12)$$

But the quadratic forms in the left and right-hand sides of (1.12) coincide (see Theorem 2.1<sup>/1/</sup>), so

$$\tilde{h}'[\psi] = \tilde{h}[\psi]. \quad (1.13)$$

From the uniqueness of the self-adjoint operators associated with the forms  $h'[\psi]$ ,  $\tilde{h}[\psi]$  (1.13) (see proposition 1.1) it follows that  $H' = H(\Lambda^N)$ , hence (see Remark 1.2):

$$\text{g.s.s. - } \lim_{L \rightarrow \infty} H(\Lambda^N) = H(\Lambda^N). \quad (1.14)$$

Therefore, in the present section we have proved the following

**Theorem 1.1.** Let  $H_L(\Lambda^N) = H_0(\Lambda^N) + U_N^L$  be a self-adjoint cut-off Hamiltonian corresponding to the nonsingular  $N$ -particle interaction  $U_N^L(x_1, \dots, x_N)$  then, for the cut-off

parameter  $L$  going to infinity, the sequence  $\{H_L(\Lambda^N)\}$  converges to the Hamiltonian  $H(\Lambda^N)$  strongly in the generalized sense.

Now we are interested in statistical mechanics of systems defined by  $H_L(\Lambda^N)$  and  $H(\Lambda^N)$ . As a first step we mention that from (1.14) the convergence of  $\exp(-\beta H_L)$  follows immediately

**Corollary 1.4.** For  $\beta > 0$ :

$$s - \lim_{L \rightarrow \infty} \exp(-\beta H_L) = \exp(-\beta H) \quad (1.15)$$

uniformly for  $\beta$  in any finite interval of the positive axis  $R_+^1$ .

It is clear that (1.15) is insufficient for the proof of the convergence of partition functions  $Z_\beta[H_L(\Lambda^N)]$  to  $Z_\beta[H(\Lambda^N)]$ . But in the next section we will show that (1.15) and some properties of the sequence  $\{H_L(\Lambda^N)\}$  allow us to prove the convergence of  $\{\exp(-\beta H_L)\}$  in the trace-class topology.

## 2. CONVERGENCE THEOREM FOR PARTITION FUNCTIONS $Z_\beta[H_L(\Lambda^N)]$

To treat the quantum statistical mechanics in a bounded region  $\Lambda \subset R^v$  of an arbitrary shape it will be very useful

**Proposition 2.1.** (Weyl's min-max principle, see, e.g., Ruelle<sup>/3/</sup>). Let  $A$  be a self-adjoint operator bounded from below. Let

$$\mu_n(A) = \inf_{\substack{M \\ \dim M = n}} \left\{ \sup_{\substack{\psi \in M \subset Q(A) \\ \|\psi\| = 1}} (\psi, A\psi) \right\}. \quad (2.1)$$

Then either (a)  $\mu_n$  is the  $n$ -th eigenvalue from the bottom of the spectrum  $\sigma(A)$  (counting multiplicity) or (b)  $\mu_n = \inf \sigma_{\text{ess}}(A)$ , where  $\sigma_{\text{ess}}(A) = \sigma(A) \setminus \sigma_{\text{disc}}(A)$ , here  $\sigma_{\text{disc}}(A)$  is the discrete part of the spectrum  $\sigma(A)$ . In particular,  $\sigma_{\text{ess}}(A) = \phi$  if and only if  $\lim_{n \rightarrow \infty} \mu_n(A) = \infty$ .

Now we recall the definition of trace-class operators  $\mathcal{A}_1$ .

**Definition 2.1.** (see, e.g., Reed and Simon /4/). Let  $\mathcal{B}(\mathcal{H})$  be the space of all bounded operators on a separable Hilbert space  $\mathcal{H}$ . The Banach space  $\mathcal{A}_1 \subset \mathcal{B}(\mathcal{H})$  of compact operators with finite  $\|\cdot\|_1$ -norm:

$$\|A\|_1 = \sum_{k=1}^{\infty} \lambda_k < \infty, \quad A \in \mathcal{A}_1, \quad (2.2)$$

where the  $\lambda_k$  denote the non-zero repeated singular values of  $A$  (i.e., the non-zero eigenvalues of  $|A| = \sqrt{A^*A}$ ), is called the trace-class and  $\|\cdot\|_1$  is the trace-norm.

In particular for any positive self-adjoint operator  $A \in \mathcal{A}_1$

$$\|A\|_1 = \text{Tr } A = \sum_{k=1}^{\infty} (\psi_k, A\psi_k) = \sum_{n=1}^{\infty} \mu_n(A), \quad (2.3)$$

where  $\{\psi_k\}$  is any orthonormal system in  $\mathcal{H}$  and  $\{\mu_n(A)\}$  are eigenvalues of  $A$  (counting multiplicity). These preliminaries allow us to prove the following statement which defines statistical mechanics of the system under consideration (see section 1 and /1/).

**Lemma 2.1.** Let  $\Lambda \subset \mathcal{R}^V$  be a bounded region of an arbitrary shape and  $U_N$  be a highly singular  $N$ -particle interaction corresponding to "point" hard core particles (see section 1 /1/). Hamiltonian  $H(\Lambda^N)$  of the

system is defined as Friedrichs extension of the algebraic sum  $H_0 + U_N$  (see /1/), then

(i) the spectrum  $\sigma(H)$  is purely discrete,

(ii) for  $\beta > 0$   $\exp(-\beta H) \in \mathcal{A}_1$ ,

(iii) the partition function  $Z_{\beta}[H(\Lambda^N)] = \text{Tr } \exp[-\beta H(\Lambda^N)]$  is nondecreasing for  $\Lambda$ , i.e.,

$$Z_{\beta}[H(\Lambda^N)] \leq Z_{\beta}[H(\Lambda'^N)] \quad \text{if } \Lambda \subset \Lambda'. \quad (2.4)$$

**Proof.** (i) The  $N$ -particle interaction  $U_N(x_1, \dots, x_N)$  for highly singular two-body potentials with "point" hard core, acceptable in statistical mechanics, is known to be at least semibounded from below (see /1/ and section 3):

$$U_N(x_1, \dots, x_N) > -a \quad \text{for } \forall (x_1, \dots, x_N) \in \Lambda^N. \quad (2.5)$$

Therefore for  $\forall \psi \in D(H_0) \cap D(U_N)$

$$h|\psi\rangle = (\psi, H_0\psi) + (\psi, U_N\psi) \geq h_0|\psi\rangle - a(\psi, \psi),$$

or for  $\forall \psi \in Q(\tilde{h})$

$$\tilde{h}|\psi\rangle \geq \tilde{h}_0|\psi\rangle - a(\psi, \psi). \quad (2.6)$$

So, from the Weyl's min-max principle (Proposition 2.1)

$$\mu_n(H(\Lambda^N)) \geq \mu_n(H_0(\Lambda^N)) - a. \quad (2.7)$$

Let us now consider a cube  $\Lambda_+ \subset \mathcal{R}^V$  and  $\Lambda \subset \Lambda_+$ . It is easy to check that in this case the spectrum  $\sigma(H_0(\Lambda_+^N))$  is purely discrete and  $\lim_{n \rightarrow \infty} \mu_n(H_0(\Lambda_+^N)) = \infty$ . Thus the same is

true for the Hamiltonian  $H(\Lambda_+^N)$  (see (2.7)). Moreover, it is clear that for  $\Lambda \subset \Lambda_+$  the Hilbert space  $\mathcal{H}(\Lambda^N)$  is in a natural way imbedded into  $\mathcal{H}(\Lambda_+^N)$ , so if  $\psi \in D(H(\Lambda^N))$  it

is also in  $D(H(\Lambda_+^N))$ . From here and Weyl's min-max principle (Proposition 2.1), we have

$$\mu_n(H(\Lambda_+^N)) \geq \mu_n(H(\Lambda_+^N)), \quad (2.8)$$

hence  $\lim_{n \rightarrow \infty} \mu_n(H(\Lambda_+^N)) = \infty$ , i.e., the spectrum  $\sigma(H(\Lambda_+^N))$  is purely discrete.

(ii) Straightforward calculations show that for the cube  $\Lambda_+ \subset \mathcal{R}^V$   $\exp[-\beta H_0(\Lambda_+^N)] \in \mathfrak{G}_1$ , hence  $\exp[-\beta H(\Lambda_+^N)] \in \mathfrak{G}_1$  (see (2.7)). From inequality (2.8) it follows that the same is true for  $\exp[-\beta H(\Lambda^N)]$  i.e., for  $\beta > 0$   $\exp[-\beta H] \in \mathfrak{G}_1$ . Therefore (see Definition 2.1)

$$Z_\beta[H(\Lambda^N)] = \text{Tr} \exp[-\beta H(\Lambda^N)] = \sum_{n=1}^{\infty} \exp[-\beta \mu_n(H(\Lambda^N))]. \quad (2.9)$$

(iii) Let us consider  $\Lambda \subset \Lambda'$  then from the discussion of point (i) it follows

$$\mu_n(H(\Lambda^N)) \geq \mu_n(H(\Lambda'^N)),$$

thus inequality (2.4) is an immediate consequence of (2.9). This completes the proof.

**Corollary 2.1.** The cut-off in the singular interaction  $U_N$  (see (1.1)) does not change its semiboundedness property (2.5): hence

$$U_N^L(x_1, \dots, x_N) \geq -a, \quad \forall (x_1, \dots, x_N) \in \Lambda^N.$$

Therefore the self-adjoint cut-off Hamiltonians  $H_L(\Lambda^N) = H_0(\Lambda^N) + U_N^L$  (see Section 1):

- (i) have a purely discrete spectrum,
- (ii) for  $\beta > 0$   $\exp[-\beta H_L(\Lambda^N)] \in \mathfrak{G}_1$ ,
- (iii)  $Z_\beta[H_L(\Lambda^N)] = \text{Tr} \exp[-\beta H_L(\Lambda^N)]$  is a nondecreasing function of  $\Lambda$ .

**Lemma 2.2.** If  $L \leq L'$  then for the corresponding trace-class norms:

$$\|\exp(-\beta H_L)\|_1 \leq \|\exp(-\beta H_{L'})\|_1. \quad (2.10)$$

**Proof.** From corollary 2.1 for  $L \leq L'$  we get

$$H_L(\Lambda^N) \leq H_{L'}(\Lambda^N), \quad D(H_L) = D(H_{L'}),$$

then from Weyl's min-max principle (Proposition 4.1)

$$\mu_n(H_L) \leq \mu_n(H_{L'}). \quad (2.11)$$

This, together with (2.9), proves inequality (2.10).

Now we prove an important auxiliary statement, required for the proof of the main result of this section, i.e., convergence of partition functions  $Z_\beta[H_L(\Lambda^N)]$  to  $Z_\beta[H(\Lambda^N)]$ .

**Lemma 2.3.** Let  $\{A_n\}$  and  $A$  be trace-class operators with  $w\text{-}\lim_{n \rightarrow \infty} A_n = A$ . If the sequence of norms  $\{\|A_n\|_1\}$

decreases monotonously together with  $\{\|A_n - A_n^{(d)}\|_1\}$  for an arbitrary  $d \geq 1$  (where  $A_n^{(d)} = P_d A_n P_d$  and  $P_d$  is a finite-dimensional projector:  $\mathfrak{H}^{(d)} = P_d \mathfrak{H}$ ,  $\dim \mathfrak{H}^{(d)} = d$ ), then

$$\|\cdot\|_1 \text{-}\lim_{n \rightarrow \infty} A_n = A. \quad (2.12)$$

**Proof.** Every operator from  $\mathfrak{G}_1$  can be approximated in the trace-class topology by finite-rank operators. Hence for  $\forall \epsilon > 0$ , we can find such  $d(\epsilon)$ , that for  $d > d(\epsilon)$

$$\|A - A^{(d)}\|_1 < \epsilon \quad \text{and} \quad \|A_1 - A_1^{(d)}\|_1 < \epsilon. \quad (2.13)$$

Hence estimation (2.13) is valid for  $\forall n \geq 1$

$$\|A_n - A_n^{(d)}\|_1 < \epsilon. \quad (2.14)$$

Consider now  $\|A - A_n\|_1$ , then

$$\|A - A_n\|_1 \leq \|P_d(A - A_n)P_d\|_1 + \|A - A^{(d)}\|_1 + \|A_n - A_n^{(d)}\|_1. \quad (2.15)$$

But on the finite-dimensional space  $\mathcal{H}^{(d)} = P_d \mathcal{H}$  all operator topologies are known to be equivalent. Therefore, for  $n$  large enough:

$$\|P_d(A - A_n)P_d\|_1 < \epsilon.$$

This estimate together with (2.13)-(2.15) proves the lemma.

**Theorem 2.1.** Let  $\{H_L(\Lambda^N)\}$  be a sequence of cut-off Hamiltonians (see section 1), then for each  $\beta > 0$

$$\|\cdot\|_1 - \lim_{L \rightarrow \infty} \exp(-\beta H_L) = \exp(-\beta H). \quad (2.16)$$

**Proof.** Let us verify the conditions of Lemma 2.3:

(a) from Corollary 1.4. (1.15)  $w\text{-}\lim_{L \rightarrow \infty} \exp(-\beta H_L) = \exp(-\beta H)$  for  $\beta > 0$ ,

(b) for  $\forall L$  and  $\beta > 0$   $\exp(-\beta H_L) \in \mathcal{G}_1$  (see Corollary 2.1) and also  $\exp(-\beta H) \in \mathcal{G}_1$  (see Lemma 2.1.);

(c) the sequence of the trace-norms  $\{\|\exp(-\beta H_L)\|_1\}$  monotonously decreases when the cutoff parameter  $L$  increases to infinity (see Lemma 2.2);

(d) moreover, inequality (2.11) for single eigenvalues of Hamiltonians  $H_L(\Lambda^N)$  and  $H_{L'}(\Lambda^N)$  (for  $L \leq L'$ ) shows that

$$\sum_{n=d+1}^{\infty} \exp[-\beta \mu_n(H_L)] < \sum_{n=d+1}^{\infty} \exp[-\beta \mu_n(H_{L'})],$$

or (see (2.9) and Definition 2.1):

$$\|\exp(-\beta H_L) - P_d \exp(-\beta H_{L'}) P_d\|_1 < \|\exp(-\beta H_L) - P_d \exp(-\beta H_{L'}) P_d\|_1.$$

Therefore the sequence  $\{\exp(-\beta H_L)\}$  satisfies all conditions of Lemma 2.3. Hence (2.16) is valid in the trace-norm topology.

**Corollary 2.2.** The  $\text{Tr}(\cdot)$  is known to be continuous in the trace-norm topology, thus for partition functions

$$Z_\beta[H_L(\Lambda^N)] = \text{Tr} \exp[-\beta H_L(\Lambda^N)]$$

and each  $\beta > 0$ .

$$\lim_{L \rightarrow \infty} Z_\beta[H_L(\Lambda^N)] = Z_\beta[H(\Lambda^N)]. \quad (2.17)$$

The same is obviously true for the free energies  $f_L = -\beta^{-1} \ln Z_\beta[H_L]$ .

### 3. CUT-OFF PROCEDURE AND STABILITY CONDITION, LENNARD-JONES POTENTIAL

In this section we discuss a purely thermodynamic problem which one immediately faces with if a cut-off procedure is introduced. As was pointed out in <sup>[1]</sup> to ensure the correct thermodynamic behaviour (absence of collapse) the Hamiltonian  $H(\Lambda^N)$  must be stable (Ruelle <sup>[3]</sup>):

$$H(\Lambda^N) > -BN \quad \text{for } B > 0 \text{ and } \forall N \geq 1. \quad (3.1)$$

For highly singular two-body potentials  $\Phi(x)$  this means that the  $N$ -particle interaction  $U_N(x_1, \dots, x_N)$  is not

only semibounded from below (see sections 1) but satisfies the stability condition in the sense of Ruelle<sup>/3/</sup>:

$$U_N(x_1, \dots, x_N) > -BN \quad \text{for } \forall N \geq 1, \forall (x_1, \dots, x_N) \in \Lambda^N \quad (3.2)$$

and fixed  $B > 0$ .

The cut-off procedure (see (1.1)) leads to the following representation of the stable interaction  $U_N(x_1, \dots, x_N)$ :

$$U_N(x_1, \dots, x_N) = U_N^L(x_1, \dots, x_N) + U_N^+(x_1, \dots, x_N), \quad (3.3)$$

here the interaction  $U_N^+(x_1, \dots, x_N)$  corresponds to a positive two-body potential  $\Phi_L(x) = \Phi(x) - \Phi_L(x)$ . But now it is an open question whether  $U_N^L(x_1, \dots, x_N)$  is stable, at least for cut-off parameters large enough (compare Ruelle<sup>/3/</sup>). If so, then we can add to the statement of Theorem 2.1 that the sequence of cut-off Hamiltonians  $H_{L,N}(\Lambda^N)$  in (2.17), (2.18) corresponds to the stable interactions  $U_N^L(x_1, \dots, x_N)$  for  $L$  large enough.

We can verify this for the case of the widely-used Lennard-Jones potentials (12-6) in three-dimensional space

$$\Phi(x) = 4E \left[ \left( \frac{a}{|x|} \right)^{12} - \left( \frac{a}{|x|} \right)^6 \right], \quad E > 0, a > 0. \quad (3.4)$$

This potential is highly singular and repulsive at the origin and regular out of it. Thus it obviously satisfies all conditions of Theorem 2.1<sup>/1/</sup> and Theorems 1.1, 2.1, therefore for this potential the convergence (2.17), (2.18) takes place. At last, potential (3.4) is stable in Ruelle sense (3.2) (see<sup>/3/</sup> and Theorem 3.1). It can be proved that the cut-off Lennard-Jones potentials  $\Phi_L(x)$  (see (1.1) and (3.4)) for  $\nu=3$  and  $L$  large enough are stable too.

**Proposition 3.1.** (Ruelle<sup>/3/</sup>). Let two-body potential  $\Phi(x) = \Phi(|x|)$  be a continuous and positive-type functions, i.e.,  $\Phi(x) \in L^1(\mathbb{R}^\nu)$  and its Fourier transform  $\tilde{\Phi}(q) \geq 0$ , then such a potential is stable if  $\tilde{\Phi}(0) > 0$ .

**Corollary 3.1.** Let two-body potential  $\Phi(x) = \Phi_1(x) + \Phi_2(x)$ , where  $\Phi_1(x) > 0$  and  $\Phi_2(x)$  be the same as in Proposition 3.1 then  $\Phi(x)$  is stable.

**Theorem 3.1.** If  $\Phi(x)$  is a Lennard-Jones potential (5.4) in  $\mathbb{R}^3$ , then the cut-off potential  $\Phi_L(x)$  defined as in section 1 (1.1) is stable for  $L$  large enough.

**Proof.** Let us construct an auxiliary function:

$$\Phi_-(x) = 4E \left[ \left( \frac{a^2}{|x|^2 + \xi^2 a^2} \right)^6 - \left( \frac{a^2}{|x|^2 + \xi^2 a^2} \right)^6 \right], \quad (3.5)$$

then a straight forward calculation shows that for  $\nu=3$  and  $0 < \xi^2 < \sqrt[3]{2} - 1$

$$\Phi_+(x) = \Phi(x) - \Phi_-(x) \geq 0. \quad (3.6)$$

The function  $\Phi_-(x)$  (3.5) is continuous and bounded from above, so we can chose the cut-off parameter  $L$  in such a way that  $L \geq \Phi_-(0)$ , then

$$\Phi_L(x) \geq \Phi_-(x). \quad (3.7)$$

If one represents  $\Phi_-(x)$  as (see Ruelle<sup>/5/</sup>)

$$\begin{aligned} \Phi_-(x) = & 4E \left[ \left( \frac{a^2}{|x|^2 + \xi^2 a^2} \right)^3 - \sqrt[3]{2} \left( \frac{a^2}{|x|^2 + \xi^2 a^2} \right)^2 \right] \times \\ & \times \left[ \left( \frac{a^2}{|x|^2 + \xi^2 a^2} \right)^3 + \sqrt[3]{2} \left( \frac{a^2}{|x|^2 + \xi^2 a^2} \right)^2 + \sqrt[3]{4} \left( \frac{a^2}{|x|^2 + \xi^2 a^2} \right) \right], \end{aligned}$$

then one can show, that  $\Phi_{\nu}(x)$  is a positive-type function for  $\nu = 3$  and  $0 < \xi^2 < \sqrt[3]{2} - 1$ . Therefore the two-body potential  $\Phi_{\nu}(x)$  is stable (Proposition 5.1). The same is obviously true for  $\Phi_L(x)$  (see (3.7)) if  $L \geq \Phi_{\nu}(0)$ . This completes the proof.

Theorem 3.1 completes the discussion of the main result of this paper (see Theorem 2.1 and Corollary 2.2).

### ACKNOWLEDGEMENTS

The author is indebted to Dr. E.Christov, Prof. A.Uhlmann and Dr. I.Volovich for numerous useful comments and criticism. I would like to thank Prof. Ja.G.Sinai for a careful reading of the manuscript, helpful suggestions and encouragement. The support and valuable remarks of Prof. D.V.Anosov, Dr. V.K.Fedyanin and Dr. V.K.Melnikov are also gratefully acknowledged.
