In recent years, a lot of research has been performed to expand available radionuclides for immuno-PET diagnostics with  $^{64}\text{Cu}$ ,  $^{86}\text{Y}$ ,  $^{76}\text{Br}$ ,  $^{89}\text{Zr}$ ,  $^{124}\text{I}$ . Another one promising radionuclide is  $^{90}\text{Nb}$  because of its suitable characteristics: a half-life of 14.6 hours, a relative fraction of  $\beta^+$ -radiation of 53%, an average energy of  $\beta^+$  radiation of 350 keV [1]. An important task is to develop an express method for obtaining  $^{90}\text{Nb}$  radionuclide without a carrier.

Here we report an original method for isolating  $^{90}\text{Nb}$  ( $T_{1/2} = 14.6$  h) produced in  $^{93}\text{Nb}(p,4n)^{90}\text{Mo}$  reaction via  $\beta^+$ -decay of  $^{90}\text{Mo}$  ( $T_{1/2} = 5.7$  h). Niobium target was irradiated with 65 MeV protons. The separation of  $^{90}\text{Mo}$  from the irradiated target was carried out in a high-temperature tubular furnace. The thermochromatographic method provides a high yield of the mother radionuclide  $^{90}\text{Mo}$  for accumulation  $^{90}\text{Nb}$ .
